GALLSTONE OBSTRUCTION

PATHOGENESIS AND ROENTGEN MANIFESTATIONS

LEO G. RIGLER, M.D.

The recognition of the specific nature of an obstructing lesion of the bowel is a vastly important expedient in the proper management of intestinal obstruction. With the introduction of suction therapy for the treatment of acute obstruction by Wangensteen and Paine,¹ the need for exact diagnosis has become even more pressing. While it is clear that in certain cases simple mechanical obstruction of the small bowel can be treated successfully without recourse to surgery, the management of obstruction of the small bowel by decompression is not without danger, especially when the exact nature of the lesion has not been ascertained. In certain instances of diagnostic uncertainty, suction decompression of the bowel postpones the inevitable train of events and creates a false sense of security. Gallstone ileus is one of the conditions in which temporizing procedures are not indicated; once this diagnosis is established, the hazard of any procedure other than surgical intervention is well recognized.

From our own experience with gallstone obstruction, as well as from the impression gained from reported cases, it appears clear that, in most instances, an exact diagnosis of dynamic ileus due to gallstones can be determined by means of roentgen examination.

The isolated reported cases in which a preoperative diagnosis of gallstone obstruction has been made are far outnumbered by the decisions emanating from the surgical or even from the autopsy table. It is not surprising to note mortality statistics which range from 33 to 93 per cent and which average close to 50 per cent, since delay in diagnosis has long been recognized as the important cause of poor results in the treatment of intestinal obstruction. It is our opinion that the almost total failure of specific diagnosis in gallstone

obstruction prior to 1930, with the correspondingly high mortality, can be converted to a reasonably high percentage of accurate diagnoses with an inevitable improvement in the recovery rate.

INCIDENCE

The number of recognized cases of intestinal obstruction due to gallstones has been indicated by various authors as ranging from 0.4 per cent to 5 per cent² of all cases of bowel obstruction. It may be stated with certainty that the range of frequency suggested is an absolute minimum; the actual incidence will probably always remain the subject of speculation.

The pathogenesis and anatomic connections of internal fistulas have been described in some detail in a previous paper.³ Gallstones may enter the intestinal tract in one of two ways: through an internal biliary fistula or through the common duct. Erosion through the wall of the gallbladder or other parts of the biliary tract is produced by the necrotizing action of a stone, which process is in turn usually related to biliary obstruction and increased intraluminal tension. Abscess formation with adhesions and final fistula formation permit entrance of the stone into the bowel. Stones large enough to obstruct the bowel almost always enter by means of a true internal biliary fistula.

Cholecystogastric, cholecystoduodenocolic, cholecystojejunocolic and choledochocolic fistulas are relatively rare and are associated with gallstone obstruction very infrequently.

It has been well established that the most frequent connection of internal biliary fistula due to gallstones is with the duodenum, resulting in a cholecystoduodenal communication. While much is written as to the pathologic nature of such a process, it is rare that we are fortunate enough to encounter the onset of this fistulous formation at the autopsy table. A characteristic example of such an instance is the specimen shown in figures 1 and 2 which was removed at autopsy by Dr. Frank Andrus of the Minneapolis General Hospital, through whose courtesy it is here illustrated. A large stone present in the gallbladder may be seen eroding through the wall of the viscus, which was closely adherent to the first portion of the duodenum. The erosion has already extended into the lumen of the duodenum itself, so that the stone can be made out through the opened duodenum. The mechanism of the development of a fistula between the gallbladder and the first portion of the duodenum is well demonstrated in this specimen.

Next in frequency to the cholecystoduodenal type, as a source of gallstone obstruction, is the choledochoduodenal fistula. We have been able to study a patient at autopsy, following accidental death, in whom three stones measuring together 3.5 by 7 cm. had passed through the major portion of the common duct but apparently could not traverse the sphincter itself. As a result an erosion of the wall at the distal portion of the duct into the second portion of the duodenum was actively progressing toward the formation of a choledochoduodenal fistula (fig. 3). The common duct was massively dilated; when the duodenum was opened the duct could be seen invaginated into the bowel. The ampulla is seen to be elevated and appears tightly closed, while erosion of the walls of the common duct and the duodenum, preliminary to the extrusion of these large stones into the intestine, has occurred. This specimen illustrates well the massive size of stone which may pass through the duct into the duodenum and the mechanism whereby this process takes place.

It is notable that while the stone filled the entire duct down to the ampulla, the effort to pass it was being made through an entirely new orifice rather than through the ampulla itself. Microscopic examination of the major papilla and dissection of the ducts by Dr. E. A. Boyden⁴ of the department of anatomy revealed the following findings:

The lowest stone, which occupied the distended major papilla, had not entered the short undistended ampulla of Vater but was being held by hypertrophied bands of muscle representing the lowest fibers of the sphincter choledochus—that portion of the sphincter of Oddi which surrounds the intramural segment of the common bile duct. As a result of this obstruc-

diameter. By contrast, the ampulla remained narrow and only a few millimeters in length, and its sphincter was only moderately developed.

Whether a stone entering the bowel through the ampulla of the common duct can produce obstruction still remains a matter of conjecture. Wakefield, Vickers

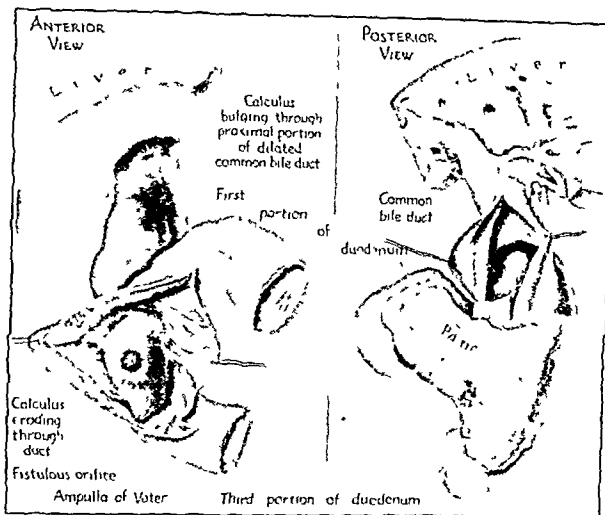

Fig. 3—Drawing of autopsy specimen taken from a patient in whom a choledochoduodenal fistula was developing from stones in the common duct. The anterior view shows the duodenum opened to exhibit the enormously dilated common duct invaginating into it. Note the ampulla of Vater tightly closed and the erosion in the wall of the duct and duodenum, where the calculus can be seen penetrating through. The posterior view shows the opened duct with the stones within it.

and Waters,⁵ for example, had never seen such a case. Courvoisier,⁶ however, stated that in 7 of 35 cases of gallstone obstruction the route taken by the stone was through the duct itself. In one of these cases the common duct was dilated to the size of the gallbladder and in another a stone 4 inches (10 cm.) in circumference had negotiated the duct and had resulted in obstruction of the bowel. Synder⁷ recently reported an unrecognized case of gallstone obstruction in which the cystic and common ducts and the ampulla were all dilated to such an extent that the index finger could easily be passed into the duodenum, yet no true fistula was present. From an examination of the literature it would appear that regurgitation of contrast material through the common duct as a result of a patent ampulla occurs about as frequently as the demonstration of choledochoduodenal and cholecystocolic fistulas. Nevertheless, there is a question as to whether most of the reported cases of communication through the orifice of the common duct are not in fact choledochoduodenal fistulas located near the end of the duct.

The possibility of error in this regard is well illustrated in figure 4, a case of choledochoduodenal fistula. Barium sulfate given by mouth is shown to extend through an opening between the first portion of the duodenum and the common duct. The distal portion of the duct is also filled with contrast material, but the distal end is tightly closed so that the barium regurgitates into the gallbladder and biliary radicles. If the spontaneous anastomosis itself were not clearly demonstrable here, this case might well have passed for one of regurgitation through the ampulla into the common duct.

tion the stones had telescoped the biliary portion of the major papilla until it reached a length of 3.5 cm. In this process the minor papilla had been drawn out onto the major papilla and the narrow slit through which the ducts normally enter the duodenum had been enlarged to an oval window 3.2 cm. in

It can be stated with considerable certainty that most stones producing occlusion enter the small bowel directly from the fundus of the gallbladder. Stones entering the colon directly seldom produce frank obstruction and are usually passed by the rectum. The important feature as concerns the present discussion is that a direct opening is established between the biliary and the intestinal tract. This abnormal connection is vastly important in the detection of the pathologic process that has preceded it since, with the exception of the relatively infrequent primary ulcerating bowel or biliary lesions, gallstones are the essential etiologic factor. Regurgitation of air or barium through the fistula into the biliary radicles permits visualization of the biliary tree because of the contrast between the liver tissue and the bile ducts.

Once a calculus has entered the intestinal tract, obstruction results if the foreign body is too large to pass the lumen of the bowel. Varying degrees of obstruction or intermittent ileus occur owing to irritation of the bowel wall and secondary spasm, even when the stone is not large enough to occlude the lumen completely. The prime factor in obstruction, however, is the presence of the stone, and the further the progress through the small bowel the greater the probability of intestinal occlusion. Only rarely does obstruction occur at as high a level as the duodenum, and in the majority of instances the terminal ileum is the final site of impaction.⁹ Naturally, the exact situation of the impaction depends, in large measure, on the size of the stone. In spite of isolated reports of unusually large stones being passed spontaneously, most writers on the subject agree¹⁰ that a stone measuring more than 25 mm. in diameter is not likely to pass through the small bowel without producing symptoms. The physical characteristics of the stone, as well as its size, require consideration, since a small stone with sharp edges can produce local irritation to the bowel wall and obstruction may be the result of spasm alone.³ In a case reported by Hinchey,¹¹ the first stone which was passed spontaneously was of greater weight and diameter than the second, which caused obstruction. The finding of a faceted stone implies the distinct possibility of the presence of a second stone, for which a search should be made. Recurrent obstruction due to a second stone during immediate convalescence has been reported in 7 instances, according to Hinchey;¹¹ Schmutzler,¹² who has likewise stressed the significance of finding a faceted stone, removed a second stone during the same operation but only after exploring the bowel above the site of the first stone.

CLINICAL CHARACTERISTICS

The clinical features of gallstone ileus have contributed little to the exact diagnosis. On the contrary, they are almost always misleading, and the confusing picture so frequently presented throws the burden of proof onto a more exacting method of diagnosis. Probably 75 per cent of the patients are women over 60 years of age. A certain percentage present a long history of intermittent gallbladder attacks preceding the acute phase, but the antecedent history of others is

devoid of biliary implication. The symptoms produced by the presence of the stone in the bowel prior to complete obstruction are of such character that they mask the picture. Some of the difficulties encountered in the clinical consideration of such patients are well demonstrated in the cases reported here.

ROENTGEN DIAGNOSIS

In a review of the literature previous to the year 1935 we were able to find but 7 cases of gallstone obstruction which had been diagnosed preoperatively by means of roentgen examination.³ Since that time we have found reports of 24 cases, including those previously reported by us, that have been diagnosed gallstone ileus and wherein the roentgen appearance was the main factor in the specificity of the diagnosis. Nevertheless numerous reports still appear, even at the present date, wherein the nature of the obstructing

lesion has only rarely¹³ or even never¹⁴ been determined before operation and wherein roentgen examination if employed at all has been confined largely to a "flat plate" of the abdomen for the purpose of confirming the diagnosis of intestinal obstruction.

The influence of roentgen examination, not only on the exact diagnosis in gallstone obstruction but on the accompanying mortality, is exemplified in a report by Petren¹⁵ from the University of Lund in Sweden. In

all 7 cases observed from 1910 to 1924 the result was postoperative fatality. From 1928 to 1939 7 cases were encountered in all of which the roentgen examination was the important feature of the diagnosis and there was only 1 death. The early determination of the probable need for surgical intervention results in the treatment of choice in most cases, namely prompt operation. As already mentioned, not only is early specific diagnosis of gallstone ileus quickly reflected in the mortality from this disease but it is of great significance in determining what part, if any, suction decompression should play in its management.

Although Wangenstein¹⁶ stated that in some instances suction will accomplish decompression and permit extrusion of the stone, he warned against the danger of procrastinating in the case of obstruction due

Fig 5 (case 1).—Roentgenogram of abdomen in supine position. 1, dilated gas filled loops of small bowel; 2, gas in stomach; 3, gas in gallbladder; 4, gas in biliary ducts. The combination of signs of intestinal obstruction with evidences of internal biliary fistula, as shown by the gas in the biliary tract, made the diagnosis of gallstone obstruction possible.

to gallstones. Persistence of intestinal distention as revealed by roentgen examination after a trial with suction indicates the necessity for operation at the earliest possible moment. Many surgeons believe that immediate operation should be done without any particular trial of suction and, at this time, Wangenstein is also of this opinion. Accordingly, if the diagnosis of gallstone ileus is specified, there are well defined limits for the use of suction; in most instances prompt surgical intervention before damage to the bowel wall and its sequelae have appeared is the best procedure.

ROENTGEN SIGNS

The roentgen examination in cases of intestinal obstruction from a gallstone may reveal any or all of the following signs:

1. Air or contrast medium in the biliary tract.
2. Direct visualization of the stone or indirect visualization of the stone by means of contrast medium in the intestine.
3. Change in position of a previously observed stone.
4. The roentgen evidences of partial or complete intestinal obstruction.

The recognition of air or contrast medium in the biliary system will, in our opinion, indicate the nature of the obstructing lesion in a higher percentage of cases than by any other single sign. In 2 cases of gallstone obstruction previously reported by us,³ this was the first direct roentgen sign noted; in Petren's series,¹⁵ in 6 of the last 7 cases wherein the exact diagnosis had been made by roentgen examination, the biliary radicles were visualized. In the literature in 22 of 36 cases of gallstone obstruction in which roentgen examination had been made, the biliary radicles were visible in the roentgenogram. Not infrequently this sign was present on the preoperative films but was not identified or recognized until after operation. Gallstones that have entered the gastrointestinal tract and which are large enough to produce obstruction practically always leave a pathway behind them permitting reflux of intestinal content. Obviously reflux of gas is the common sign found, as the administration of contrast substances, such as barium sulfate, is usually contraindicated.

Films made in both the anteroposterior and postero-anterior projections, centered over the right upper quadrant, are of greater value in eliciting this sign than are films centered over the midabdomen. The fact that no other special procedure is necessary for the demonstration of gas in the bile ducts adds greatly to the value of the finding. Usually the lower portion of the biliary tree alone is visible, and therefore the relationship of the linear or circumscribed markings to the duodenal loop is particularly important. A classic example of the roentgen findings in a spontaneous internal biliary fistula, without intestinal obstruction, has already been illustrated in figure 4. The hepatic duct and its branches are filled with gas as well as barium. Another illustration of contrast medium in the biliary tract in association with obstruction is shown in figure 8, while gas alone in the biliary tract is shown in figures 5, 6 and 7.

Because a biliary fistula tends to obliterate itself by scar formation, the absence of air in the bile ducts cannot be considered as completely eliminating the possibility of gallstone obstruction.

Regurgitation of contrast material through what has been termed "an incompetent common duct sphincter" has been observed in the presence of a stone lodged in the lower end of the common duct, and in a case of carcinomatous metastasis producing a high jejunal obstruction.¹⁸ However, the proof of an incompetent sphincter and the absence of a fistula has not been offered. Åkerlund¹⁹ and Case²⁰ have demonstrated

barium in the distal ends of the ducts in cases of chronic pancreatitis. Indurating, usually malignant lesions adjacent to the common duct are known to have permitted reflux.²¹ Emphysematous cholecystitis and cholangitis incident to infections of the biliary tract with gas forming organisms²² may rarely produce gas in the ducts. With these possible and rare exceptions the presence of contrast material or gas in the biliary tract is synonymous with fistula formation. Accordingly, the demonstration of air or barium in the bile ducts in association with intestinal obstruction (fig. 5) practically excludes any consideration other than occlusion from a gallstone.

In a certain percentage of cases, especially when clinical signs point to the possibility of gallstone ileus and when careful search is made, the stone will be directly seen in the roentgenogram of the abdomen (fig. 7). Unless considerable calcification and lamellation are present, the calculus may well escape detection, especially when the obstruction has resulted in fluid and gaseous distention of the bowel. Similarly, in such instances, the administration of barium as an aid in detection is not a recommended procedure, although it may occasionally be given in error, as in case 4. As already indicated, biliary calculi are most likely to be found in the region of the terminal ileum. The postero-anterior projection is the position of choice. In our experience, when the stone shadow is apparent the bile ducts are usually also seen, while the contrary is not true. The determination, before surgical exploration, of the quadrant occupied by the stone and its relative position in the small intestine facilitates removal with a minimum of trauma.

The disappearance of previously demonstrated gallstones or, more especially, detection of the same shadows of gallstones in the lower part of the abdomen following previous observation in the right upper quadrant is of distinct diagnostic value. However, the utilization of this sequence of events must be considered unusual as well as fortunate. In 1 of our previously reported cases our suspicion was first aroused by the failure to see a group of stones which had been quite evident during a previous examination. A similar finding was obtained in case 4 of this series. The presence of a demonstrable stone in the gallbladder which is faceted but without a sister stone may be sufficient to arouse suspicion, but it is only suggestive. Such a situation is illustrated in case 2 (fig. 6).

The roentgen evidences of intestinal obstruction are obviously also to be found. It should be noted, however, that characteristic distention of loops of the small bowel may not be demonstrable because the obstruction may be partial or intermittent. In most cases, however, the classic distention of several loops of the small bowel with gas, the unusual visibility of the small intestinal segments and the relative absence of gas in the colon may be observed. Careful study of the films will reveal the presence of the normal peritoneal markings and the absence of any free gas or fluid in the peritoneal cavity; such findings tend to militate against the diagnosis of peritonitis.

Sosman^{22a} has suggested that the perforation of a duodenal ulcer into the gallbladder, when accompanied by paralytic ileus, may produce roentgen findings closely

simulating those of gallstone obstruction. We have never encountered this problem.

For the purposes of this study 404 cases of intestinal obstruction of all types were reviewed. Among these there were 11 cases of undoubted gallstone obstruction in 10 of which a reasonably adequate roentgen examination of the abdomen had been made. In addition, we have observed 4 other cases of proved gallstone obstruction. In all of the 14 cases examined there were reasonably good roentgen signs of intestinal obstruction; in all but 1 there were evidences of gas or contrast medium in the biliary tract (figs. 5 and 6). The calculus was directly demonstrable (fig. 7) in 4 cases and showed a change in position from its previously known site in 2 cases. In 1 case the calculus produced a defect in the barium-filled intestinal shadow

Fig. 6 (case 2).—Roentgenogram of abdomen in supine position, 1, dilated loops of intestine filled with gas; 2, gas in the stomach; 3, shadow of impacted stone with facet on upper surface (this was not observed before operation); 4, faceted stone in gallbladder with gas above it, extending into biliary ducts. Presence of gas in the biliary tract, the remaining faceted stone in the gallbladder and evidences of intestinal obstruction permitted the exact diagnosis of gallstone obstruction.

(fig. 8). In 2 cases additional stones were visible in the gallbladder. It should be noted that the diagnosis was not made in all these cases from the roentgen examination, but the failure to make the correct diagnosis was not due to the absence of the signs in the roentgenogram but rather to failure to detect the signs because of unfamiliarity with the syndrome.

REPORT OF CASES

In order to illustrate the characteristic features of this condition 4 cases from this group are reported in some detail:

CASE 2.—A woman aged 62 was admitted to the University Hospital complaining of abdominal crampy pains, nausea and vomiting of two days' duration. The pain began in the mid-

21. Rees, C. E.: Duodenocolic Fistula with Incompetent Sphincter of Oddi, *J. A. M. A.* **100**:496-497 (Feb 18) 1933.

22a. Sosman, M. C.: Personal communication to the authors.

abdomen, radiated indefinitely to the back and was associated with nausea and vomiting. There had been no bowel movements for three days. In the past twelve hours, however, her condition had improved considerably, and the pain had disappeared.

Physical examination on admission revealed little evidence of distention, tenderness or spasm and no bowel sounds could

obstruction could be made from the first film, despite the absence of any very remarkable distention of the small bowel. It is notable that in the last twelve hours before entrance the patient had become distinctly better. This is typical of many cases of gallstone obstruction and is one of the characteristics of the symptomatology of this condition.

The single roentgenogram of the abdomen (fig. 6) revealed the evidences of intestinal obstruction, the remaining stone in the gallbladder and gas in the biliary tract. Careful study of the film after the operation revealed the large impacted stone in the ileum. This shadow, however, was so faint that it probably could not have been recognized without certain knowledge of its presence. The facet on its superior surface could also be identified.

The disappearance of the stone remaining in the gallbladder without any evidence of it becoming obvious by the patient's condition indicates the ease with which smaller stones may be passed.

CASE 3—A woman aged 75 was admitted to St. Andrew's Hospital complaining of pain in the right upper quadrant, abdominal colic and vomiting, all of which had been present for one week. The past history was of no significance. The physical examination suggested dynamic intestinal obstruction.

With the latter in mind, we performed duodenal suction and instituted intravenous administration of chlorides, with good symptomatic relief.

Fig 7 (case 3)—Roentgenogram of abdomen in supine position. 1, loops of small bowel distended with gas; 2, gas and suction tube in stomach; 3, laminated dense shadow characteristic of gallstone in right lower quadrant; 4, gas in biliary ducts. The stone is here directly visualized together with the evidences of intestinal obstruction and of an internal biliary fistula.

be made out. The clinical impression was that this was a subsiding cholecystitis.

The roentgen examination of the abdomen (fig 6) showed only two small loops of bowel distended with gas. A typical faceted gallstone could be made out in the region of the gallbladder, and above this an area characteristic of gas was clearly shown. The finding of intestinal distention, faceted gallstone and the presence of gas in the gallbladder led to a definite diagnosis of gallstone obstruction.

Shortly after this some evidence of extrarenal uremia appeared, duodenal suction was started and surgical exploration was undertaken by Dr. O. H. Wangenstein.

When the abdomen was opened a gallstone 3.5 by 3.5 by 3 cm, smoothly faceted at each end, was found in the ileum on the right side of the abdomen. This was removed by enterotomy and the intestine closed.

Reexamination with roentgenograms of the abdomen two weeks after the operation showed the gallstone previously observed in the gallbladder to have disappeared. Although the stools were examined, this stone was never recovered, but repeated roentgen examinations thereafter indicated that it undoubtedly had passed during convalescence.

The deceptive character of the symptoms of this patient is illustrated by the fact that she was seen by two members of the resident staff on her entrance, neither of whom thought that she had intestinal obstruction or any illness of serious consequence. Yet on roentgen examination the exact diagnosis of gallstone

Fig 8 (case 4)—Roentgenogram of abdomen in prone position, following administration of barium enema and barium meal. 1, barium in the stomach; 2, barium in the colon; 3, gas in distended loops of small bowel; 4, barium in severely distended loops of small bowel; 5, barium and gas extending into biliary ducts from fistula; 6, barium surrounding gallstone in small bowel. In this instance the diagnosis of gallstone obstruction could be made from the direct evidence of an internal biliary fistula, direct evidence of intestinal obstruction and the indirect visualization of the stone itself.

A simple roentgenogram of the abdomen with the patient supine was made at the bedside two days later. This revealed distended loops of small bowel, a laminated dense shadow in the left side of the pelvis resembling a gallstone and a few

areas of lessened density over the liver, indicating gas in the biliary ducts. Reexamination the following day (fig. 7) exhibited the same conditions except that the gallstone had moved somewhat to the right.

Abdominal exploration was carried out by Dr. Charles Hallberg. Near the distal portion of the ileum was found a gallstone measuring 3 cm. in diameter completely occluding the bowel. The mucosa was ulcerated and perforation was impending. The calculus was removed by enterotomy and the patient made an uneventful recovery.

This case presents three of the roentgen signs of gallstone obstruction, namely gas in the biliary ducts, visible gallstone in the lower part of the abdomen and signs of intestinal obstruction. Not only was the exact diagnosis established by roentgen examination but the position of the stone was localized, permitting a surgical approach with a minimum of effort. From the appearance of the bowel it seemed clear that perforation might have occurred if surgical therapy had been further delayed.

CASE 4.—A woman aged 70 was admitted to the University Hospital following a minor accident. She had had a long history of cholecystitis and cholelithiasis; there were various other complaints over a period of many years, none of which were closely related to the present condition. Roentgen examination six years earlier had revealed multiple large stones in the gallbladder.

About three weeks before entrance the patient had had an accident and injured her back. Roentgen examinations of the spine and pelvis gave essentially negative results. She came in at this time complaining of pain in the back for which she was kept under observation. There were also evidences of mental deterioration. Two days later she complained of abdominal pain and had some vomiting, but for the next two days the patient was fairly comfortable. On the day of the operation there was some tenderness in the abdomen and the patient was complaining of nausea and distention. Because of the numerous complaints which she had made in the past, the history of accident and her mental state, the clinical impression was that there was no real pathologic condition of the abdomen.

Intestinal obstruction was not considered, but because of the possibility of some lesion of the digestive tract roentgen examination of the colon with a barium enema and of the gastrointestinal tract with barium meal was undertaken. A significant distention of the loops of small bowel was observed (fig. 8) and within a loop of the ileum a defect was apparent. The shadow of the gallstone was no longer visible in the right upper quadrant. The extension of the barium into a fistula communicating with the biliary tract and some gas in the biliary ducts served to demonstrate conclusively the entire diagnosis, namely gallstone obstruction, with a large stone in the bowel surrounded by barium and an internal biliary fistula.

Surgical exploration of the abdomen was undertaken and the distended loops of small bowel were demonstrated. A stone measuring 3.5 by 3 by 3 cm., one surface of which was smoothly faceted, was found about 20 cm. from the ileocecal valve, where it was impacted. It was removed by enterotomy, the small bowel was closed and the patient made an uneventful recovery.

This case was extraordinary in view of the high degree of obstruction despite symptoms which were insufficient to indicate a serious clinical condition. The giving of barium was, of course, an error, although in this instance it apparently produced no ill results. The demonstration of a gallstone as a defect in the barium shadow is illustrated in this particular case. In addition there were the disappearance of previously observed shadows of stones in the gallbladder area, the presence of barium in the internal biliary fistula, gas in the bile ducts and roentgen evidences of intestinal obstruction

SUMMARY

1. Two cases were observed at autopsy in which the manner of development of a choledochoduodenal and a cholecystoduodenal fistula could be demonstrated.

2. The specific signs which permit a roentgenologic diagnosis of this condition are evidences of dynamic ileus, presence of gas or contrast medium in the biliary tract and direct or indirect visualization of the calculus.

3. In 13 of 14 cases of gallstone obstruction in which roentgen examination was made, the exact diagnosis could have been made from the roentgenograms alone.

4. It is important to recognize the exact nature of an obstructing lesion of the bowel in order to determine whether suction therapy or immediate surgery should be undertaken.

5. Because gallstone obstruction is an indication for immediate intervention, every effort should be made to recognize its characteristic roentgen signs.

ABSTRACT OF DISCUSSION

DR. JAMES T. CASE, Chicago: I have always been skeptical about gallstones passing through the natural channels. I have seen undoubted gallstones that patients claimed had passed and I have always insisted that they must have passed through some spontaneous fistula. I have had several personal cases in which gallstones were passed through fistulous openings later demonstrated in the opened abdomen. I am glad to note that Drs. Rigler, Borman and Noble voice an objection to the general unselected use of suction therapy. I think I see a tendency to employ that method in all cases of ileus, whereas there are conditions in which it should not be used. The method of passage of the stone from the gallbladder into the lumen of the digestive tube has been strikingly illustrated by the authors. There are 2 of my cases of special interest in which a gallstone passed in this manner. In 1 the stone passed from the gallbladder into the stomach, and the calculus was so large that it could not get through the pylorus. It was recognized on my gastrointestinal study as a foreign body free in the stomach, and operation showed that it was a gallstone and that it had passed into the stomach through a spontaneous cholecystogastrostomy. In the other one a gastroenterostomy had been performed previously. A spontaneous cholecystocolostomy and a spontaneous cholecystoduodenostomy occurred, and a gallstone which lay in the duodenum was found when an operation was performed later. In the study of suspected acute intestinal obstruction we should not be content to depend on the gas shadows in the intestine to the exclusion of the use of opaque materials. I know that there are many who feel that it is objectionable to introduce barium or bismuth in any form into the digestive tube in the presence of suspected obstruction. But there is now available a means which I myself have employed for a number of years; namely, the oral administration of the aqueous solution of thorium dioxide, which can be given to any patient without any fear of complications. It will enable one to visualize safely the small intestine even in the face of obstruction. Within four hours one can get good visualization, especially if it is given very cold and if the patient is kept recumbent on the right side in bed to facilitate the evacuation of stomach contents.

DR. LEO G. RIGLER, Minneapolis: There is no doubt, as Dr. Case said, that stones will pass through the intestinal tract without interference, but the risk in waiting for them to pass spontaneously is so great that it should not be undertaken. I should like to reemphasize that the history in gallstone obstruction is very often unreliable. The combination of signs that I have described and with which every one, I am sure, is familiar, namely gas in the biliary ducts plus the evidences of intestinal obstruction, is practically specific regardless of whether or not the stone can be seen. In our experience it is much more specific and much more reliable than either the history or the physical findings in this particular type of intestinal obstruction.

ANESTHESIA FOR SURGERY ABOUT
THE HEADURBAN H. EVERSOLE, M.D.
BOSTON

This discussion is not intended as an exhaustive treatment of the subject of anesthesia for surgery about the head but rather as a discussion of some of the technical problems with which the anesthesiologist is confronted when an operation is to be performed in this region of the body. In addition, a detailed description of two methods of administering anesthesia for surgery about the head is to be presented. These methods have been developed in an attempt to meet certain requirements which are important and to overcome some of the difficulties that are frequently encountered during the course of anesthesia for operations in this region of the body.

There are many factors that the anesthesiologist must consider if he is to select the proper anesthetic agent and method of its administration for any type of surgery. Some of these factors have a peculiar significance when the operation is to be performed in the region of the head. Some of the more important of these may be considered under one of the following heads: (1) proper preparation of the patient for operation, (2) selection of the proper agent, (3) employment of a method of administering this agent that will insure an adequate and unobstructed airway at all times, (4) facilities readily available for the treatment of respiratory and circulatory depression, (5) an anesthetic technic which will in no way hamper the work of the surgeon, (6) precautions against explosion when inflammable anesthetic agents are being used and (7) adequate protection for the patients' eyes.

Since this discussion deals primarily with the technical management of anesthesia for operations about the head, no detailed consideration will be given to the preparation of the patient for operation. Obviously, there should be an adequate preoperative general physical examination, with a careful estimation of the surgical risk. Not only the choice of anesthesia but often the choice and magnitude of the operation is affected by a proper appreciation of the hazards which may be presented by the patient's condition. In addition, adequate preoperative treatment will often favorably affect certain serious physical conditions which may be present.

Essentially the same rules apply to the selection of preoperative medication for patients who are to have some type of operation about the head as apply when the operation is to be performed in any other part of the body. Proper attention should be paid to drug idiosyncrasies, age, sex and the physical condition of the patient. It must be borne in mind that the respiratory mechanism may be seriously upset in patients who have increased intracranial pressure or in any patient during the course of intracranial surgery. For this reason, any drug which may cause respiratory depression should be used cautiously in patients with increased intracranial pressure or on whom any type of intracranial operation is to be performed.

In the selection of the proper anesthetic agent for any type of surgical procedure, the question of adequate oxygen, as well as the explosion hazard, must be considered. Unsupplemented nitrous oxide and oxygen is the only commonly used inhalation anesthetic mixture

that is entirely noninflammable. Since nitrous oxide is such a weak anesthetic agent that it does not permit the administration of sufficient oxygen to allow for the maintenance of anesthesia without some degree of anoxia, this agent is seldom used unsupplemented. Of course, the addition of ether or cyclopropane as a supplemental agent makes the mixture inflammable. Ethylene shares with cyclopropane and ether the property of being explosive and, in addition, shares with nitrous oxide the property of being so weak as not to permit the administration of sufficient oxygen with it to guarantee freedom from anoxia at all times. Both ether and cyclopropane are sufficiently potent as anesthetic agents to permit the administration of oxygen in amounts large enough to insure adequate oxygen, regardless of the depth of anesthesia. It therefore becomes quite evident that safeguards against an explosion in the operating room when an inhalation anesthetic is being used take on the nature of precautions rather than the use of nonexplosive agents. The danger of explosion is greatly increased when the surgeon uses a high frequency electrosurgical unit for removal of tissue or for coagulating bleeding vessels. High frequency currents may cause induced electrical charges to be built up on other pieces of apparatus or on the patient with the consequent danger of a spark, in addition to the obvious point of danger where the cutting or coagulating point comes in contact with the tissue. The only danger that is presented by the low voltage actual cautery is that of the glowing end of the cautery itself. The low voltage actual cautery or the high frequency coagulating apparatus should not be used in or around the mouth when inflammable anesthetics are being used. In addition, the high frequency apparatus should not be used at all if cyclopropane or ether vapor and oxygen is being administered, as with the carbon dioxide absorption technic. When any type of electrosurgical apparatus or cautery is to be used, ether vapor and air is probably much safer than ether vapor and oxygen and is certainly safer than cyclopropane and oxygen. Experiments done by Dr. J. W. King of the Massachusetts Institute of Technology have shown that no mixture of ether and air will explode with the violence that some mixtures of ether and oxygen do. Neither will any mixture of ether and air explode with the violence that all explosive mixtures of cyclopropane and oxygen will.¹ In addition, further precautions should be taken, such as placing a screen between all anesthetic connections and the operative field, and the delivery of the exhaled gases at a point several feet from the site of operation. Even though ether vapor and air is less explosive than ether vapor and oxygen, this must not be taken to indicate that this mixture is entirely free from the hazard of explosion.

One of the shorter acting barbiturates such as pentothal or evipal administered intravenously is quite satisfactory for operations that will probably not exceed thirty minutes in length. Obviously, the use of this method of anesthesia eliminates all the dangers of explosion.

One of the most important factors to be considered in the management of any type of anesthesia is the maintenance of an adequate and unobstructed airway at all times. This is particularly important for any type of surgery about the head. For this reason an endotracheal tube should be in place before any extensive surgery is begun in this region of the body. However, the mere presence of an endotracheal tube is not in

From the Department of Anesthesia, the Labey Clinic.

1. King, J. W.: Personal communication to the author.

itself a guaranty that the patient will have an adequate respiratory exchange. A method of administration should be employed that will not only permit the anesthetist to observe the depth and character of the patient's respirations but also enable him to render effective treatment should any marked degree of respiratory

Fig 1—Patient with apparatus in position for administration of intermittent intravenous anesthesia, with nasal endotracheal tube in place

depression become manifest. During the course of intracranial surgery, particularly in the posterior fossa, marked disturbances of respiration are not at all uncommon. The anesthetist must be on the alert for signs of disturbed respiration and should have facilities immediately available to carry out artificial respiration for an indefinite length of time should it be necessary.

The problem of circulatory depression presented by patients on whom operations about the head are performed in no way differs from the problem of circulatory depression presented when an operation is performed in any other region of the body. When a long or shocking surgical procedure is anticipated, or if during the course of any surgical procedure there is considerable blood loss or evidence of impending shock, a continuous intravenous drip of fluid should be started. This affords a means of replacing fluid and is also a route for the administration of blood should a transfusion be necessary. In the actual treatment of shock there is no fluid that is as valuable as whole blood. If this is not immediately available, a 5 or 10 per cent solution of dextrose in distilled water may be used. The use of physiologic solution of sodium chloride in the treatment of low blood pressure and shock is probably of only transitory value. Adrenergic drugs such as epinephrine, neosynephrin, ephedrine and pitressin are occasionally indicated. At best their action is only temporary and they should be used only in an emergency to support a failing circulation until intravenous fluid and transfusion can be instituted.

Another important factor which may easily be neglected in the management of patients on whom operations in the region of the head and face are performed is the protection of the eyes. A serious keratitis which may even result in an opacity of the cornea may develop from an injury to the eye during an operation. Extreme care should be taken to prevent irritating agents such as iodine and alcohol from getting in the eyes. Furthermore, safeguards should be taken to prevent drapes from being forced down against the eyeball. Even in the absence of an irritating agent, if an eye is left open

during the course of an operation a rather serious keratitis may develop as a result of the drying of the cornea. If the draping is such that the anesthetist cannot readily see the eyes at all times, they may be protected by filling them with boric acid ointment and covering with gutta percha which is molded firmly into position by means of a sponge soaked in hot water. This is an excellent method for the protection of the eyes of patients suffering from exophthalmos.

A fundamental principle which should guide the anesthesiologist in planning anesthesia for any type of operation is that he should so devise and place his apparatus that it in no way hampers the work of the surgeon. It should be an almost invariable rule that the surgeon should not have to modify his technic or hamper himself for room to work in order that the anesthetist may use a particular piece of apparatus. Anesthesia is sufficiently flexible and there is available a large enough variety of drugs and methods to enable an anesthesiologist, even without an unusual amount of ingenuity, to devise methods whereby he can safely and adequately maintain anesthesia for an almost unlimited length of time without, so to speak, getting in the surgeon's way.

In view of some of the technical problems mentioned earlier in this discussion, anesthesia for surgery about the head can be roughly classified under three main heads: (1) operations of short duration (thirty minutes or less) in which the development of any degree of respiratory difficulty is quite unlikely, (2) operations of longer duration during which the surgeon will not use any type of high frequency surgical apparatus or the actual cautery and (3) operations of longer duration during which either the actual cautery or some type of high frequency coagulating apparatus may be used.

For surgical procedures which are superficial and will probably not require more than thirty minutes to complete, one of the shorter acting intravenous barbiturates, such as pentothal or evipal, has proved quite satisfactory. These may be administered in a 5 per cent solution or, as suggested by Lundy and his associates,² a 2.5 per cent solution offers less chance of delayed phlebitis or, if some of the solution is inadvertently injected outside the vein, there is less danger of severe tissue reaction. The apparatus described by

Fig 2—Diagrammatic sketch of apparatus shown in figure 1

Nicholson and Sise³ for the administration of intravenous anesthetic agents has been quite satisfactory and has the advantage of being simple and inexpensive.

2. Lundy, J. S.; Tuohy, E. B.; Adams, R. C., and Mousel, L. H. Annual Report for 1938 of the Section on Anesthesia. Including Data on Blood Transfusion, Proc. Staff Meet., Mayo Clin 14: 273-284 (May 3) 1939.

3. Nicholson, M. J., and Sise, L. F.: Pentothal Sodium Anesthesia for Encephalography, New England J. Med 222: 994-996 (June 13) 1940.

This apparatus consists of a thick walled rubber tube, about 1 foot in length, with a stopcock and glass adapter on one end for the needle and a metal adapter for the syringe on the other end. The needle can be placed directly in the vein or, if an intravenous drip apparatus is already in place, it may be shunted into the system by means of a Y connection. It should be borne in mind

Fig 3—Apparatus for the administration endotracheally of ether vapor and air. Note respiratory indicator over end of exhalation tube. Ether chamber illustrated is a Richardson bottle

that a precipitate may be formed if pentothal is added to dextrose solution. If this drug is to be added to an intravenous drip, the intravenous fluid should be physiologic solution of sodium chloride.

Except for short procedures (ten minutes or less) an endotracheal tube should be inserted when intravenous anesthesia is employed for surgery about the head. The patient is first anesthetized with a small amount of the barbiturate solution and the throat is then carefully sprayed with a 10 per cent solution of cocaine. Great care should be taken to spray the epiglottis and larynx. The tip of the atomizer should then be passed down between the vocal cords, and the inside of the trachea sprayed with the cocaine solution. A rubber endotracheal tube of the Magill type is now passed through the nose into the trachea and secured in place by a small piece of adhesive tape. Some sort of frame should now be placed over the end of the tube and held in position by means of adhesive tape to hold the drapes away from the end of the tube, where they might form an obstruction. An ordinary ether mask of the Yankauer type is very satisfactory for this purpose (figs. 1 and 2). This method has the disadvantage of not permitting any type of artificial respiration other than manual pressure on the chest wall and for this reason should not be employed when respiratory difficulties are anticipated. On the other hand, this method does have the advantage of not presenting any explosion hazard.

For longer operations, during which the surgeon will not use any type of high frequency electrical apparatus or cautery, cyclopropane or cyclopropane in combination with ether or ethylene administered by the carbon dioxide absorption technic is preferable. With the use

of a circle type filter for carbon dioxide absorption the inhalation and exhalation tubes may be extended as far as desired, in order to allow the anesthetist to keep well away from the operative field, without any danger of building up a carbon dioxide concentration that would be harmful to the patient. In addition, there is no necessity for a bulky piece of apparatus near the patient's head which might be in the surgeon's way.

When this method is used it is desirable to have a snug fit of the endotracheal tube into the trachea so that all of the patient's respirations will be carried out through the tube. For this purpose an inflatable rubber cuff of the type described by Guedel and Waters⁴ is very satisfactory. If an inflatable rubber cuff is not available; the same purpose can be accomplished by packing moist gauze which has been impregnated with surgical lubricant tightly around the endotracheal tube. This method has the disadvantage of increasing the hazard of aspiration of vomitus, should the patient vomit while the apparatus is in place.

For longer procedures during the course of which the surgeon is likely to use some type of high frequency electrical apparatus or the actual cautery, ether vapor and air is probably safer from the standpoint of explosion than cyclopropane-oxygen or ether vapor and oxygen.¹

For the administration of ether vapor and air, over long periods of time, a semiopen type of apparatus may be used. The objectives in mind when this apparatus was designed were (1) an adequate airway at all times, (2) ether vapor mixed with air, (3) delivery of the exhaled gases at a point several feet away from the site of operation, (4) elimination of all danger of building up increased pressure in the lungs and (5) a method affording a simple and easy way of administering artificial respiration. This apparatus consists of (1) a source of compressed air, (2) a chamber for the vaporization of ether, (3) rubber tubing at least $\frac{1}{2}$ inch in diameter

Fig 4—Patient with apparatus in place for the administration endotracheally of ether vapor and air. Ether chamber illustrated is a Connell anestheticometer. Note respiratory indicator over end of exhalation tube and intravenous drip for the administration of fluid.

and long enough to reach from the patient's head to the ether vaporizer at the foot of the table, for the delivery of the ether vapor laden air to the patient, (4) a V shaped connection for attachment of the inhaling and exhaling tubes to the hilt of the endotracheal tube, (5)

4 Guedel, A. E., and Waters, R. M.: A New Intratracheal Catheter. *Anesth. & Analg.* 7: 238 239 (July-Aug.) 1928

an endotracheal tube, (6) a large caliber exhaling tube and (7) a wisp of cotton or small piece of tissue paper to act as a respiratory indicator over the end of the exhaling tube (fig. 3).

The most satisfactory source of compressed air is from a jet in the operating room with a compressor and storage tank elsewhere in the hospital. However, if this

Fig. 5.—Diagrammatic sketch of apparatus shown in figure 4.

is not available, a motor or foot pump may be used if they will deliver greater than approximately 12 liters of air a minute. In addition, air that has been compressed into large cylinders may be used, although this method is obviously quite expensive. The chamber for the vaporization of ether should be so designed that varying portions of the air can be shunted over the ether without varying the volume of flow to the patient. A useful apparatus for the administration of varying concentrations of ether vapor in the inspired air is the Connell anesthetometer.⁵ This is a semiautomatic apparatus which is very efficient in the maintenance of a relatively level plane of ether anesthesia. This apparatus is calibrated so that the concentrations of ether vapor delivered to the patient may be read off directly in millimeters of mercury partial pressure of ether vapor.

A much less expensive apparatus for the vaporization of ether is the so-called Richardson bottle,⁶ which costs only a small fraction of the price of the anesthetometer. Although it is not nearly so automatic as the anesthetometer, this apparatus has proved satisfactory, and with a little experience one may become proficient in maintaining an even plane of anesthesia with it. With the Richardson bottle, ether is contained in an ordinary Ball-Mason fruit jar. The lid of the jar is so designed that a constant flow of air can be maintained through it, and by means of a screw setting variable amounts of the air may be allowed to pass over the ether. With the anesthetometer there is a rheostat controlled electric plate for heating the ether vapor. With the Richardson bottle the ether vapor is heated by merely setting the jar in a basin of warm water.

It is important that the tubes leading to and from the endotracheal catheter are of rather large caliber in order that there may be no difficulty in delivering a sufficient amount of air to satisfy the patient's tidal respiration, and that there may be no resistance to expiration. Any of the commonly used types of endotracheal tubes may be employed. The flexible metal tube described by Woodbridge⁷ is satisfactory.

The respiratory indicator on the distal end of the exhalation tube is important. By watching its movements the anesthetist may obtain considerable information as to the character of the respirations. Furthermore, this respiratory indicator serves to inform the anesthetist

when the flow of air delivered to the patient is less than his respiratory volume. When this is true the patient will inhale from the exhaling tube and draw the indicator into the end of the tube. When this occurs it should be immediately corrected, since a flow of air less than the patient is breathing results in his breathing back and forth into the exhaling tube, thus building up carbon dioxide and, in addition, anoxia may develop. As long as an adequate flow of air is maintained there is practically no limit to the length to which the inhalation and exhalation tubes may be extended, thus enabling the anesthetist to be well out of the field of operation and yet be able to observe enough of the vital signs to evaluate adequately the patient's condition (figs. 4 and 5).

The semiopen type of apparatus just described is well adapted for artificial respiration. If the anesthetist's hand is placed over the end of the exhalation tube at intervals of about fifteen times a minute the air pressure will inflate the lungs, while the weight of the chest wall will take care of expiration. A safety valve in the circuit calibrated to open when 12 mm. of mercury pressure is reached obviates the danger of building up too much pressure in the lungs with this method of artificial respiration. When the semiopen method is to be used, the patient is first anesthetized with cyclopropane or ethylene and the transition to ether gradually made. After a depth of anesthesia has been reached that will permit the introduction of an endotracheal tube with facility, the larynx and trachea are sprayed with a 10 per cent solution of cocaine and the tube is inserted. The endotracheal tube is firmly anchored in position by means of adhesive tape, and the V connection from the ether vaporizer is attached to the hilt of the tube.

The administration of moderate doses of tribromethanol in amylene hydrate (70 to 80 mg. per kilogram of body weight) rectally prior to the induction of anesthesia makes for a smoother induction and probably diminishes the total amount of ether necessary to maintain anesthesia. Because of the danger of circulatory collapse it is advisable not to use tribromethanol in amylene hydrate if the operation is to be carried out with the patient in a sitting position.

605 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. FREDERICK W. CLEMENT, Toledo, Ohio: My associates and I choose one of three agents: avertin with amylene hydrate, pentothal sodium or a gas-oxygen mixture. We use avertin with amylene hydrate occasionally and pentothal sodium for short operations. For many years our anesthetic of choice has been nitrous oxide. Dr. Eversole said: "Since nitrous oxide is such a weak anesthetic agent that it does not permit the administration of sufficient oxygen to allow for the maintenance of anesthesia without some degree of anoxia, this agent is not used unsupplemented." Unfortunately, too little attention is paid to the many advantages of nitrous oxide-oxygen anesthesia. With nitrous oxide or gas-oxygen anesthesia there is usually some anoxemia present, but that does not imply that there will be any severe or troublesome degree of anoxia. The use of the endotracheal catheter operations about the head and neck provides a free and open airway, and 100 per cent oxygen may be administered at any time during the operation for the treatment of respiratory depression. The gases may be delivered under any desired amount of positive pressure and respiration thereby supported. The operative field is left free, and there is absolute freedom from the hazard of explosion. A gas-oxygen mixture may be used for either short or long anesthesia. Within the last year continuous gas-oxygen anesthesia was

induced intratracheally in 2 patients for brain operations. The operation on 1 patient lasted nine and a half hours, and the other operation lasted over eleven hours. At the end of operation, both patients reacted rapidly and were awake within fifteen minutes. What other inhalation agent could be used to duplicate this performance? One factor often overlooked in connection with gas-oxygen mixtures is that as the anesthesia progresses the percentage of oxygen in the mixture must be increased as rapidly as possible without disturbing the level of anesthesia. If this is not done there is grave danger of development of prolonged oxygen want. Our method of using gas-oxygen anesthesia for surgical procedures about the head and neck is to induce anesthesia with a face mask, pass an intratracheal tube by the nasal route, then connect with an adapter to the intratracheal tube or use a nasal inhaler over the tube, the endotracheal tube being used primarily to insure an open airway. Dr. Eversole's paper brings out two valuable points: protection of the patient's eyes during the operation and care to prevent malposition from kinking the endotracheal tube, with consequent obstruction of the airway.

DR. B. BURDELL SANKEY, East Cleveland, Ohio: Adequate support of the circulation for poor risk patients undergoing surgical procedures about the head and neck cannot be overemphasized. Especially in long or shocking procedures it is well to insert a large bore needle in a suitable vein before the operation is started. A continuous, slow, intravenous drip of saline solution may be connected, and if or when the need arises blood plasma or whole blood may be more readily and more quickly administered. A word of caution should here be said about using pentothal sodium or evipal soluble for even short operations about the nose and throat in which even a small amount of bleeding may be encountered. Serious difficulty may be experienced in maintaining an adequate exchange due to collection of blood in the base of the throat. Unless an endotracheal tube is inserted, there are probably other agents which are more suitable for this type of procedure. A relatively simple and satisfactory method of producing adequate anesthesia for certain operations about the head and neck is to employ morphine and scopolamine hydrobromide in divided doses. This method has proved useful for some fractures about the face and jaw for which otherwise an endotracheal setup might be advisable. For certain operations on the eye it is frequently advantageous to combine local with intravenous anesthesia. When employing pentothal sodium for such operations it has been our custom first to spray the nose and throat with a 2 per cent solution of pontocaine hydrochloride. This facilitates the use of a pharyngeal airway, which is inserted after the induction of anesthesia with pentothal sodium. A local anesthetic may then be infiltrated about the orbit, or cocaine may be applied directly to the eye. Oxygen may be administered by a nasal inhaler which is fitted directly on the pharyngeal airway. A 50 per cent mixture of nitrous oxide and oxygen may likewise be administered through the inhaler in conjunction with pentothal sodium.

DR. W. OTIS MCQUISTON, Iowa City: The anesthesia staff at the State University of Iowa's hospitals have recognized the fact that nitrous oxide asphyxia has been used for years for anesthesia. We maintain that with proper individualized premedication surgical anesthesia can be induced and maintained with adequate oxygen. Less than 20 per cent oxygen is never used in our clinic.

DR. URBAN H. EVERSOLE, Boston: I want to thank Drs. Clement, Sankey and McQuiston for their valuable additions to my paper. Dr. Clement has aptly emphasized a most important point in the administration of any anesthetic agent. The safety of any method of administration is measured not entirely in terms of the agent itself but rather in terms of the ability and experience of the man who employs it. I have no doubt that nitrous oxide administered by Dr. Clement is much safer for the patient than it would be when administered by me. Any of the agents discussed may be perfectly safe in the hands of anesthetists who are proficient in their use. I doubt that statistics are available which would properly evaluate the relative hazard presented by varying degrees of oxygen want and the hazard of explosion when inflammable anesthetic agents are used. I am sure, however, that unsupplemented nitrous oxide-

oxygen anesthesia does not allow for the administration of oxygen in as high a concentration as is usually considered normal. The suggestion that the endotracheal tube should be one in which there is no danger of kinking is important. I use the flexible metal tube described by Woodbridge, and with this tube there is no danger of kinking or collapsing. Dr. Sankey's discussion of some of the problems associated with anesthesia for operations on the eye was most interesting. The limitation of time permitted only a sketchy mentioning of some of the many problems involved in the administration of anesthesia for surgical procedures about the head.

USE OF SILVER PICRATE IN THE TREATMENT OF VAGINITIS: A FIVE YEAR STUDY

FORMATION OF A VAGINITIS UNIT IN A
GYNECOLOGIC CLINIC

JOHN D. CORBIT Jr., M.D.

ROBERT McELROY, M.D.

AND

J. H. CLARK, M.D.

PHILADELPHIA

The development of a treatment regimen with silver picrate for patients with *Trichomonas vaginalis* vaginitis in the gynecologic clinic of the Philadelphia General Hospital five years ago has brought about several interesting changes in the clinic. Prior to that time routine smears were not made and the patients were handled in a more or less haphazard fashion. With the revival of interest in this parasite, many types of treatment have been developed, but in following the literature one finds few reports from clinics in which any one form of treatment has been kept up for a considerable length of time. In many places the search for the organism is made under unfavorable conditions and the diagnosis is not always confirmed by laboratory methods. It is our purpose in this paper to state just how the situation in relation to *Trichomonas* infection and vaginitis in general has been managed at this hospital.

DIAGNOSIS

If a good microscope is available for use in the clinic, specimens need not be sent to the laboratory, and the diagnosis of *T. vaginalis* vaginitis becomes easy. With the patient in the lithotomy position, the vulva is inspected and an unlubricated speculum inserted. No lubrication is used on the glove or speculum because usually there is enough vaginal secretion to make it unnecessary, and more specifically because most of the common lubricants are dehydrating agents and render the organism immobile. The cervix and vagina are then inspected and a specimen of the discharge is taken on a cotton swab. The swab is immersed in a test tube containing about 3 cc. of physiologic solution of sodium chloride. This dilutes the material for examination without interfering with the motility of the organism. This motility establishes the diagnosis when a drop of the solution is examined first under the low power and then under the high dry lens of a microscope. In this study cultures were made on all specimens and morphologic studies were made on stained smears. These are not necessary when one becomes familiar with the appearance of the organism in the saline drop-

From the Philadelphia General Hospital.

The nursing staff and the social service workers in the gynecologic dispensary of the Philadelphia General Hospital gave valuable assistance during the course of this study.

let. When the history and clinical appearance are suggestive and yet no motile organisms can be demonstrated, it is important to ask the patient whether she has had a douche just before coming in for examination. If so, she is asked to return for reexamination after having gone at least forty-eight hours without one.

The clinical diagnosis of *T. vaginalis* vaginitis is suggested by a history of discharge and itching and by the finding of reddening about the labia and vaginal mucosa with small punctate hemorrhagic spots in the mucosa, especially on and about the cervix. The usual discharge is thin, frothy, yellowish gray and malodorous. This may be regarded as typical, but the organism is found many times when few of these conditions are present.

The diagnosis of vaginal moniliasis also may be made from a wet preparation and confirmed by streaking a slant of Sabouraud's agar for culture. The discharge here is thick, white and caseous and the vaginal infection is often associated with dermatitis and excoriation about the labia. Most of the patients we see are pregnant at the time.

PREPARATION FOR TREATMENT

When the diagnosis has been established, it is necessary in most instances to clean out whatever mucus and debris are present in the vagina. This is done so

TABLE 1.—Incidence of *Trichomonas Vaginalis* and of *Monilia Albicans* Infection (1935-1940)

* Since these figures are obtained from a group of patients in a definite gynecologic group, the percentages would probably be smaller if taken from a more general hospital group.

that when the medication is applied it can act directly on the infected tissue without having to penetrate a mass of debris. One of the most common agents used for this cleansing is tincture of green soap. However, this has not proved satisfactory in our hands. The soap is mildly irritating to inflamed mucosa, and this, combined with the necessary mechanical scrubbing, has not only failed to remove the mucus efficiently but has caused bleeding in some cases. The cleansing technic recently reported by Savitz and his associates¹ has been used in this study. A cotton sponge, saturated with the kaolin-alumina mixture (aluminum hydroxide-colloidal kaolin suspension to which have been added minute quantities of thymol, eucalyptol and menthol) is used to swab over the vaginal mucosa and cervix. This is washed out with another sponge saturated with sterile water, followed with a dry sponge. In this way, mucus and debris can be efficiently removed without danger of irritation or bleeding, either to eroded or to normal tissues.

This thorough cleansing is important because recurrence of infection can occur from organisms harbored in this debris. In this connection, it is especially impor-

tant to clean out the plug of mucus from the cervix. Cleansing also reveals the extent of the lesions and the true appearance of any pathologic condition that is present. In moniliasis, this technic is helpful in removing the white caseous patches without trauma to the inflamed tissues underneath. When erosions and other

95	...	5.9	...	Did not respond to treatment

lesions of the cervix are encountered, the usual methods are employed to clear these up before continuing with treatment for the vaginitis. Reinfection may occur from organisms which may persist if these lesions are untreated.

TREATMENT

We have continued with the plan of treatment outlined by Buxton and Shelanski in 1935.² The reasoning that led to the adoption of this technic was as follows: The successful use of silver nitrate in *T. vaginalis* vaginitis had been reported, but although it possesses strong germicidal qualities its corrosive action makes it undesirable for repeated application. Picric acid has been used³ and has a mildly germicidal and soothing effect. It also fixes tissues and tends to render them bacteriostatic, but its germicidal action is comparatively weak. Silver picrate combines the germicidal and soothing action of these two without the corrosive action of the nitric acid salt. It has strong fungicidal and protozoacidal properties with a specific action against *T. vaginalis* in vitro in a 1:1,000 dilution in approximately three minutes.⁴

We use the combined powder insufflation and suppository technic recommended by Golub and Shelanski,⁵ which is briefly as follows: Five Gm. of 1 per cent silver picrate in kaolin^{5a} is insufflated into the vagina at the first clinic visit. This is done with the Shelanski insufflator. The patient is given six silver picrate suppositories^{5a} (2 grains [0.13 Gm.] of silver picrate in a boroglyceride-gelatin base) and instructed to

is repeated weekly until the symptoms are relieved and smears are negative for the organism. Two insufflations suffice in most cases, but in some cases it is necessary to give additional insufflations. If tests on a patient remain negative for three consecutive menstrual periods after cessation of treatment, she is considered cured and discharged as such.⁶

VAGINITIS UNIT

The vaginitis unit of a gynecologic clinic need not be separated from the rest of the clinic, but when space is available it is helpful to do so. In our survey, we used a separate room with two examining tables and a bench for the microscope and other laboratory equipment. Under these conditions a physician, with the help of only one nurse, may see a great many patients in a relatively short time. Smears and cultures are taken on all new patients admitted to the general clinic if there are any symptoms or signs of vaginitis. If no other pathologic condition requiring more urgent treatment is found, they return on their next visit to the vaginitis unit. They are followed here until cured or referred back to the general clinic.

It has been interesting to note that some patients who come to the clinic primarily for relief of pelvic pain are cured after treatment in the vaginitis unit. Patients having moderate retroversion or vaguely tender adnexal masses, who complain of pain in the lower part of the abdomen and back ache and who also have vaginitis it has been our custom to refer first to the vaginitis unit and to plan further therapy after the vaginitis and cervicitis have been cleared up. More than a third of these patients are relieved of all complaints when they return. In this way we believe that a certain number of unnecessary pelvic operations have been prevented.

RESULTS

Since the vaginitis unit has been set up we have been able to reduce the time required for each clinic visit. The entire procedure, consisting of diagnosis, preparation, insufflation and instruction, takes but five minutes for each patient. Also, we have been able to bring about more than a 50 per cent reduction in the number of necessary clinic visits.

The incidence found in a series of routine examinations is given in table 1. The cases of trichomoniasis were found chiefly in the gynecologic clinic; several cases, however, were referred from the antepartum clinic. Most of the cases of moniliasis, however, were referred from the antepartum clinic, and only a few were found on routine gynecologic examinations.

Diagnosis in this entire survey was done by smear and culture. In clinical work, however, it is necessary to make the diagnosis only by smear.

From table 2 it may be seen that of 1,646 patients treated for trichomoniasis 86.2 per cent were cured within two to three weeks, 3.2 per cent in more than three weeks, 4.7 per cent lapsed treatment and 5.9 per cent did not respond permanently to treatment, and the focus of infection could not be determined, even though the possibility of Bartholinitis or Skeneitis due to *T. vaginalis* was ruled out. Some of these patients had several recurrences before being finally rid of the infection.

Table 3 shows that among 151 patients with vaginal moniliasis 91 per cent were cured within three weeks, 4 per cent required treatment more than three weeks,

2 per cent lapsed treatment and 3 per cent did not respond to treatment. Some of these patients were too near the time of delivery to continue treatment.

Some patients with a decidedly alkaline urine tend to be irritated by silver picrate therapy. To date we have observed but 2 patients who might be classed as being sensitive to the drug. It is believed that these patients had picric acid sensitivity. There have been no untoward reactions in all the other patients treated with silver picrate.

CONCLUSIONS

A method of management of cases of vaginitis has given satisfactory results in 94.1 per cent of 1,646 cases of trichomoniasis and in 97 per cent of 151 cases of moniliasis.

The establishment of a vaginitis unit and a routine for the management of these cases has resulted in an economy of time for the clinic personnel and a higher percentage of satisfactory results for the patients.

Unnecessary pelvic surgery has been prevented in some cases.

RECENT INVESTIGATIONS ON GONOCOCCIC VAGINITIS

JOHN L. RICE, M.D.
Commissioner of Health

ALFRED COHN, M.D.

ARTHUR STEER, M.D.

AND

ELEANOR L. ADLER, M.D.

NEW YORK

The New York City Department of Health, with the cooperation of the United States Public Health Service, in 1938 began research on gonococcic vaginitis with the object of studying diagnosis, criteria of cure and epidemiology and of evaluating different methods of treatment. This report summarizes the more important conclusions reached and expresses our agreed opinion and that of the members of the advisory committee¹ who so ably guided the work.

Since the inception of this study, 381 (22.2 per cent) of 1,715 children examined were found to have gonococcic vaginitis. The infected children were examined once a week until the diagnostic laboratory procedures had given negative results for about eight successive weeks, after which they were examined at monthly intervals. Material for examination was obtained by inserting a glass female catheter containing saline solution into the vagina. Portions of the same specimen of exudate were used for smear and for culture.

DIAGNOSIS

Nonspecific vaginitis and gonococcic vaginitis can be differentiated only by smear and/or culture. As can be seen from chart 1, cultures are far superior to smears, especially in the chronic stage of the infection.

This study was supported in part by the Milbank Memorial Fund, the New York Foundation and the Health Research Fund, Inc.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

From the Department of Health, City of New York (Drs. Cohn and Steer) and the Department of Pediatrics, New York University and the Children's Medical Service of Bellevue Hospital (Dr. Adler).

1. The advisory committee for the study consisted of Drs. John L. Rice, Commissioner of Health; Edward L. Keyes, Chairman; Eleanor L. Rice, Reuel A. Benson; Casper G. Burn; Walter Clarke; Alfred Cohn; Adolph Jacoby; Robert M. Lewis; John F. Mahoney; Ralph S. Muckenfuss; Bernard Pacella; Percy S. Pelouze, and Theodore Rosenthal.

6. Hesseltine, H. C.: Fallacies of *Trichomonas Vaginalis* Vaginitis: Streptococci as Etiologic Agents, *Am. J. Obst. & Gynec.* 26: 46-53 (July) 1933. Karnaky, K. J.: Why Does *Trichomonas Vaginalis* Recur? Report of Thirty-Eight Cases, *Urol. & Cutan. Rev.* 42: 812-813 (Nov.) 1938.

CRITERIA OF CURE

It was arbitrarily agreed that children to be considered cured must be clinically normal and that at least seven consecutive smears and cultures made during a period of at least sixteen weeks must show no gonococci. Prolonged study revealed that this was satisfactory for 92.2 per cent of the 204 patients studied intensively. Results of tests of 16 became positive again more than sixteen weeks after they had first become negative. It was impossible to say whether these patients had a recurrence of the original disease or a new infection.

STUDIES ON THERAPY

Forty-one children were observed who were not given any form of treatment. Some recovered within a short time, 54 per cent by the tenth week and 87 per cent by the twenty-eighth week after the beginning of observation (chart 2). This is definite evidence that spontaneous cure of the disease may occur in the majority of patients. These children have remained normal for an average of forty-five and nine-tenths weeks and have had an average of fourteen and four-tenths negative smears and cultures.

TREATMENT WITH ESTROGENIC SUBSTANCES

Thirty-three children were treated with estrogenic substances (amniotin and diethylstilbestrol). The 12 (36 per cent) who were cured were treated for an average of fifty-four and five-tenths days. Comparison with the control series showed that bacteriologically cure was no more frequent among patients given this form of therapy than among the untreated patients. However, definite clinical improvement followed shortly after the institution of treatment.

TREATMENT WITH SULFANILAMIDE

Fifty-three children were treated with sulfanilamide. The 23 (43 per cent) who were cured were treated for an average of nine and six-tenths days. This drug gave definitely better results than would be expected without treatment (chart 3).

TREATMENT WITH SULFAPYRIDINE AND SULFATHIAZOLE

Because the results of therapy were approximately the same, the 20 children treated with sulfathiazole and the 57 treated with sulfapyridine were combined into a single group. The 67 (87 per cent) who were cured received treatment for an average of six and seven-tenths days. These drugs were effective for rectal infection when it was present. Sulfathiazole appeared to be the drug of choice, because it produced fewer toxic reactions (nausea and vomiting) than did sulfapyridine.

For the present it is suggested that children be given ½ grain (0.03 Gm.) per pound (0.5 Kg.) of body weight per day, with a maximum of 30 grains (1.9 Gm.) per day for seven to ten days.

It must be pointed out that, of the 10 children who were not cured by treatment with sulfapyridine or sulfathiazole, only 2 showed gonococcic vaginitis, either clinically or by smear or culture, during the first four weeks after therapy was stopped. An average of eight and two-tenths weeks elapsed before the failure of treatment was recognized in these 10.

EPIDEMIOLOGY

Vaginitis is generally believed to be extremely contagious, requiring only superficial contact for its transmission. Outbreaks in epidemic form have been

described. Infected children are therefore excluded from institutions such as schools, general hospitals, institutions for the care of children and convalescent homes.

However, the question of widespread dissemination of this disease in public places requires reconsideration. In more than five years of search no evidence was found of an epidemic in a New York school although many children with fresh infections attended these schools before a diagnosis was made. During the course of this study no instance of an epidemic in any institution or orphanage was discovered. Isolated cases did occur, but always the suspicion arose that some break in technic had spread the disease or that children had been admitted with unrecognized infection. In one overcrowded dormitory where the possibilities of isolation were remote, only 2 of 90 feeble-minded girls were found to have the disease.

As a result of the foregoing observations, it seems likely that many of the epidemics of vaginitis reported in the past were not due to the gonococcus. There is further evidence that this infection is not as contagious

Chart 1.—Accuracy of diagnosis by smear and culture in proved cases (proved by culture) of gonococcic vaginitis.

as has been heretofore believed. In the vaginitis ward of a hospital there were children with acute gonococcic vaginitis, children who were cured and being observed for proof of cure and others who had been admitted to the ward for observation but were later shown not to be infected. No restrictions were placed on these children, and they were not isolated one from another. Over a period of years no instance of disease in the noninfected children was observed. Furthermore, during two different periods of several months all the children in the ward used the same toilets without causing new infections. As many as 8 infected children with profuse vaginal discharge were placed on the same toilet in rotation, and several cultures were made of material taken from the toilet seat. On only one of eighteen occasions were gonococci recovered, and then only a few colonies could be found in one culture. As far as we know, no instance of transmission of the disease by way of the toilet seat has ever been proved.

Investigation of parents and siblings revealed that the probable source of infection in the majority of cases was

an infected adult in the home. Fifty per cent of a group of parents who prior to examination believed themselves healthy were found to be infected. Another important method of transmission that was disclosed is associated with sexual curiosity and experimentation. Thirty-five per cent of infected girls between the age of 6 years and puberty admitted sexual contacts.

Chart 2.—Gonococcic vaginitis, untreated (control) group: spontaneous cures occurring without treatment in 41 cases during twenty-eight weeks' observation.

It may be concluded that the transmission of the disease requires intimate contact between infected adult or child and non-infected child. Contaminated fomites, such as rectal thermometers, enema tips, diapers, towels and linen may possibly be factors in the spread of the disease.

RECOMMENDATIONS

It is recommended that children not be excluded from

school because of gonococcic vaginitis except during the stage of profuse discharge. The recommendation is based on the fact that the only intimate contact among children would be by way of the toilet seat, which has not been shown to be a factor in the transmission of the disease. It should be understood that sex play should be prevented by adequate supervision. Furthermore, treatment with sulfathiazole would cure most infected children within a few days, so that even with the restriction based on the presence of discharge the children could return to school quickly.

With this form of treatment, vaginitis as a rule is not a disease requiring hospitalization. Even children in

such children noninfectious. It must be remembered that during the first few days aseptic technic should be practiced by the nursing staff. In the care of infected children, instruments and fingers come into intimate contact with the genitals of the patients and if not thoroughly cleansed may possibly infect another child. When a trained, efficient nursing staff is not available isolation of the children in separate wards is to be preferred.

It is further recommended that cultures be used for diagnosis and as criteria of cure and that the follow-up study for the determination of cure last at least sixteen weeks. It is important that family contacts should be examined to discover the source of infection and to prevent reinfection. One should also bear in mind that older children may have been infected during sex play or as a result of sexual intercourse.

125 Worth Street.

ABSTRACT OF DISCUSSION

DR. REUEL A. BENSON, New York: From the pediatric point of view the results of this research are as revolutionary as they are brilliant. Dr. Rice and his co-workers have made a valuable contribution. For many years gonococcic infection in little girls has been a rather disreputable waif, going from the pediatrician, the gynecologist, to the urologist, asking for help and never getting it. Public health officials generally have shunned it. Some years ago the superintendent of schools in New York City filed charges saying that forty-eight children in the public schools had been inoculated with "a loathsome disease" in the public hospitals. The health commissioner investigated that report and exonerated the hospitals, but he did say that the problem of the spread of the disease had never been solved anywhere. Now it has been solved. This paper represents the ideal in practical research. It will serve as a guide for health officers as well as for hospital officials. The dictum that vaginitis "spreads like wildfire" is no longer true, and this, we thought, was about the only "fact" we had in connection with the disease. Hospitalization, local treatment and exclusion from school for long periods now all go by the board. Incidentally, this investigation makes possible great financial saving. At the Metropolitan Hospital in New York we have in the past hospitalized as many as 50 or 100 children with gonorrheal vaginitis, sometimes for months, giving them local treatment which was always bad psychologically, costing the city of New York thousands of dollars annually, and most of these children did not have gonococcic vaginitis at all, although we didn't know that. As a result of the information derived from this investigation we have an average of only 10 or 15 cases, and these are of homeless children coming from child caring institutions. There is also evidence in this report to indicate that a similar study of adult females might lead to equally brilliant results. Undoubtedly the female with gonorrhea is the one who spreads the disease. If such a group could be studied as intensively with cultures, smears and attention to what I would call the "gonorrheal nest," the individual who spreads the disease to the children, we might ultimately have great results in prevention.

DR. GOODRICH C. SCHAUFFLER, Portland, Ore.: I regard the work of Dr. Cohn and his associates, supplemented by that of Dr. Robert Lewis, as a classic commitment. It is sound and permanent, if somewhat revolutionary doctrine. Having so stated, perhaps I may offer some friendly criticisms: Dr. Cohn has proved that gonorrheal vaginitis apparently cures itself almost as well as it can be cured by any medication; and then he assures us that one practically cannot transmit the disease by ordinary contacts. We put ourselves in a dangerous position if we accept his commitments as given here, and if we go ahead and translate them literally into our practice. I don't believe that Dr. Cohn really means that we may actually dispense with treatment or precautions in relation to the transmission of infec-

PER CENT CURED AS COMPARED WITH SPONTANEOUS CURES IN CONTROL GROUP DURING THE SAME PERIOD.	DURATION OF TREATMENT
SULFATHIAZOLE OR SULFAPYRIDINE 43 CASES — 87% CURED UNTREATED ⁽¹⁾ (CONTROLS) — 10% CURED	6.7 DAYS
SULFANILAMIDE 63 CASES — 43% CURED UNTREATED ⁽¹⁾ (CONTROLS) — 12% CURED	9.6 DAYS
ESTROGENIC SUBSTANCE 43 CASES — 36% CURED UNTREATED ⁽¹⁾ (CONTROLS) — 4% CURED	54.6 DAYS

Chart 3.—Course of gonococcic vaginitis in treated and untreated groups. Control group (1): 41 untreated children, with cures occurring during twenty-eight weeks' observation.

institutions for the care of children need not be sent to a hospital, since treatment by the attending physician or a neighboring clinic would be sufficient. Children who must be hospitalized because of complications or the occurrence of concurrent diseases need not be placed in separate isolation wards but may be treated for the complicating factor without regard to the vaginitis. Treatment with sulfathiazole would soon make

tion. For example, his group of so-called untreated patients were handled quite differently from an "untreated group" in the usual sense. These patients were hospitalized under hygienic surroundings and were examined, cleansed and cultured frequently. I have always stressed the value of simple vaginal invasion with distention of crypts in the interest of drainage, incidental to the use of estrogenic suppositories and medicated ointment. There is a mechanical factor of importance here; therefore these children in ideal surroundings, treated weekly or semiweekly by vaginal manipulation, are not typical of a group left entirely alone, and we must not allow any one to suppose that we must not use the strictest precautions in relation to cross infection. In relation to infection from toilet seats, I have this to say: Six children with gonococcal infections, doubtless ordinarily cleansed, were passed on and off a toilet seat; then cultures of the toilet seat were carefully taken, and in only one instance were isolated colonies of *Neisseria* found. Uninfected children were not infected by the use of these seats. I think it has been proved that the culture material available to date is unsatisfactory. It seems likely, then, that culture may be at fault here. Also whereas six children might be exposed safely to such tests, the seventh or the seventieth might be the unfortunate victim. In any event, I don't believe we can dispense with all these precautions. I don't agree that institutionalization is not dangerous from several angles. I am certain that there is a danger in foundling home care. As for hospitalization in general, I admit that, save in exceptional circumstances, it is unsatisfactory from both a practical and a psychological point of view.

DR. HAVEN EMERSON, New York: Twenty-six years ago Dr. William H. Park made a study of the bacteriology of toilet seats in schools in which children with gonococcal vaginitis had been found, and he never found any such organism on the toilet seats. That was done in numerous schools in Brooklyn and Manhattan with the thoroughness and controls characteristic of the work of Dr. Park. We must recognize that one of the most valuable results of specific chemotherapy is the abbreviation of the period of communicability. If a child's period of communicability can be reduced from twenty-six or twenty-eight weeks to one week, a great gain has been accomplished in control of the disease. The risk of careless handling in an institution for children or orphan home is of a different order from what is found in a hospital. The hospital is operated on the basis of a medical aseptic technic. I should be inclined to suggest that we do not change the sanitary code of the city of New York with regard to the exclusion of children with purulent vaginal discharges from any nurseries, not because we believe the association of those children in a hospital would lead to infection but because of obvious risks of infection where less exact and careful measures for bacterial cleanliness are observed.

DR. CARL A. WILZBACH, Cincinnati: I had the privilege more than fifteen years ago of starting a children's vaginitis clinic in the Cincinnati Health Department. In this clinic we soon discovered that the follow-up examination from these children was a splendid method of finding new infectious cases. We made an effort every time we had one of these children to get the parents into the clinic for examination, and we found, just as Dr. Cohn has said, that the source of the infection was usually the adult, the mother or the father, or an older person in the family; so, in addition to the other fine things that have been contributed by this paper, let us remember the case finding possibilities.

The Sulfonamides Not Yet Fully Appreciated.—Living within the epoch, we have hardly yet appreciated the benefits which the new therapy has conferred and will continue to confer upon medicine and mankind. Vaccination, antityphoid inoculation and salvarsan may one day seem small discoveries beside that of sulfanilamide, which was first shown to have therapeutic possibilities in the case of streptococcal infections only six years ago.—Ryle, John A.: *The New Chemotherapy*, *Guy's Hosp. Gaz.* 55:222 (Sept. 6) 1941.

SULFATHIAZOLE IN THE TREATMENT OF GONORRHEA IN WOMEN

PAUL F. FLETCHER, M.D.

ORA JAMES GIBSON, M.D.

AND

S. EDWARD SULKIN, Ph.D.

ST. LOUIS

The encouraging results obtained by many investigators¹ treating gonorrhea in the male with drugs of the sulfonamide series and the relatively few reports² concerning the use of these drugs in the treatment of gonococcal infection in women suggested the need for further investigation of this problem. Soon after sulfathiazole, the thiazole derivative of sulfanilamide, became available to the medical profession for clinical trial a study was undertaken to determine the efficacy of this drug in a carefully controlled group of hospitalized women. Studies on toxicity in animals by Van Dyke, Greep, Rake and McKee³ and Long, Haviland and their associates⁴ indicated that the drug could be safely used clinically under carefully controlled conditions. It was found that the sulfathiazole compound was approximately one third less toxic than sulfapyridine, based on 50 per cent end point titrations in mice. Metabolic studies have shown that sulfathiazole is more rapidly metabolized and undergoes less conjugation than sulfapyridine. In view of the comparative toxicity and metabolism of these two compounds McKee and her associates⁵ concluded that sulfathiazole is a more desirable therapeutic agent than sulfapyridine.

PLAN OF STUDY

This investigation was conducted over a period of eleven months during which time 194 gonococcal infections in women were studied. The patients investigated were drawn from a special unit of the Venereal Disease

From the Venereal Disease Control Service and Laboratory Section of the St. Louis Health Division.

Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

Control Service of the St. Louis Health Division, concerned only with the diagnosis of venereal diseases in prostitutes and inmates of bawdy houses. A special city ordinance⁶ providing for the hospitalization and treatment of prostitutes infected with any of the venereal diseases made this study possible.

Every woman showing clinical evidence of gonococcal infection confirmed by laboratory tests was isolated for a period of at least two weeks. Specimens for smears and cultures were obtained on the first and second day of isolation, after which treatment was continued for from four to twelve days. Laboratory examinations were discontinued from the second to the eighth day and were resumed nine days after medication was started, at which time daily specimens for smears and cultures were taken until the fourteenth day. If the last three consecutive smears and cultures were negative, the patient was discharged from the hospital and placed on "quarantine parole." Accordingly, the patient was required to report to the clinic at weekly intervals for pelvic examination and laboratory study. If clinical and laboratory examinations

hours before being transferred to an appropriate culture medium. Immediate refrigeration is essential to inhibit the growth of contaminants which would render subsequent isolation of the gonococcus more difficult. The culture technic used has been described in detail by Sulkin and Gottlieb.⁷ The exudate suspensions were plated on proteose-peptone no. 3-hemoglobin agar and incubated at 36 C. in an atmosphere containing 10 per cent carbon dioxide for forty-eight hours. The oxydase test described by Gordon and McLeod⁸ was used for identifying the gonococcus colonies. Smears were made from the oxydase-positive colonies and stained by an approved Gram technic. In a few instances more complete identification included the carbohydrate fermentation test and the Thomson⁹ alkali solubility test.

A minimum of lubricant, consisting of a dilute solution of tincture of green soap, was used on the speculum in obtaining specimens in this series. Gillick, Sulkin and Stephens¹⁰ feel that the use of K-L jelly or similar lubricants may be responsible for the unsatisfactory results frequently obtained when the cultural method is employed in the diagnosis of gonococcal infections.

continued negative for twelve consecutive weeks, the patient was considered "clinically cured." Many returned to the clinic for longer periods, thus permitting follow-up study for six months or more. If a positive smear or culture was obtained at any time during this "parole period," the patient was again hospitalized and subjected to another complete study. The condition was considered a recurrence of the original infection, regardless of the length of time since termination of the first course of treatment, unless reinfection could definitely be established.

DIAGNOSIS

To collect specimens for the smear and cultural methods of examination the urethral meatus was cleansed with sterile cotton, then pressure was applied to the urethra and Skene's ducts to obtain adequate material for examination. The exudate was collected on sterile cotton swabs. Cervical specimens were obtained by compressing the portio between the blades of a Graves speculum to force the contents of the deep racemose glands into the cervical canal. This exudate was also collected on a sterile swab. The urethral and cervical specimens were placed in the same tube containing 1 cc. of broth (proteose-peptone no. 3) to prevent the exudate from drying. The suspensions were kept in a refrigerator for not longer than six

OUTLINE OF TREATMENT

Two methods of treatment were used. The first 100 patients received sulfathiazole¹¹ and vaginal instillations of beta-lactose boric acid. The second group of 94 patients received only sulfathiazole. The administration of sulfathiazole was the same in the two groups. A clinical criterion by which to govern the daily dose of sulfathiazole had not been established at the time this study was begun, hence an arbitrary dose was decided on. Sixty grains (4 Gm.) was given in divided doses of 15 grains (1 Gm.) each four times a day for five consecutive days. This daily dose was approximately equivalent to 1/2 grain (0.03 Gm.) a pound. Medication was begun as soon as the diagnosis of gonorrhea was established, without regard for the phase of the menstrual cycle. A second course of treatment was given as a routine during the following period of menstruation. If menstruation occurred during the first administration of the drug, medication was not repeated during the subsequent period. When it

did not occur before the patient was discharged from the hospital she was given enough sulfathiazole for another course of therapy to be taken during her next menstrual period. This precaution was taken because preliminary observations suggested that menstruation may be responsible for an exacerbation of the infection.

Every patient showed some degree of cervical infection. Since many infections were associated with extensive erosions, an endeavor was made to restore and maintain a normal vaginal acidity (p_H 4.0 to p_H 4.2). The vaginal suppositories of beta-lactose boric acid described by Roblee¹² containing 80 per cent beta-lactose and 20 per cent boric acid powder in no. 11 veterinary capsules were used. One capsule was inserted into the vagina each evening at bedtime for twelve consecutive applications. Douches were not

referred back to us because smears and cultures were still positive. A second course of sulfathiazole was started but had to be discontinued after the first day because the reaction mentioned was well developed on the morning of the second day. Laboratory examinations on the second patient were negative after one course of sulfathiazole alone. Menstruation ensued fifteen days later so that a second course of treatment was started but had to be stopped after the first day because severe and uncontrollable nausea and vomiting developed. It stopped spontaneously twenty-four hours later. The patient was discharged sixteen weeks later classified as a clinical cure.

Seven patients showed mild nausea and malaise which were relieved by the administration of 7.5 grains (0.5 Gm.) of sodium bicarbonate with each dose of

permitted during this period. Specimens for smears and cultures were taken during the last three days of local therapy. Beta-lactose was not repeated under any circumstances, nor was it ever given during menstruation.

TOXIC MANIFESTATIONS

Toxic manifestations were noted in 13 (6.7 per cent) patients. In 2 instances the drug was discontinued, in 1 because of a severe cutaneous reaction developing in the form of a painful urticarial rash. The circumstances associated in this instance were unusual. On admission to the hospital it was found that in addition to a gonococcal infection the patient had a pregnancy of approximately eight weeks gestation. No reactions were noted with the first regular five day course of sulfathiazole. Two days after therapy was completed signs of abortion threatened and she was immediately transferred to the City Hospital. Fourteen days after the completion of a spontaneous abortion she was

sulfathiazole, thus permitting them to continue treatment. Three additional patients suffered mild fever reactions and complained of chilly sensations and nausea, but the temperature remained normal. They, too, were able to continue their treatment when given sodium bicarbonate. One patient had a mild urticarial reaction but was able to continue taking the drug.

Similar toxic manifestations resulting from the use of drugs of the sulfonamide series have been reported by Flippin, Schwartz and Rose,¹³ Greenwood,¹⁴ Mahoney, Wolcott and Van Slyke¹⁵ and others.

EPIDEMIOLOGY

Sixty-three per cent of the patients were white and 37 per cent were Negroes; 46 per cent were between the ages of 21 and 25, 20 per cent were between 26

and 30, 14 per cent were between 31 and 35 and 18.5 per cent were under 21. The youngest was 18 and the oldest 60.

Syphilis was present in 26 per cent of the 194 patients treated for gonorrhea. Condylomata acuminata were noted in 5 patients and a diagnosis of fibromyomata uteri was made in 5 others. Chancroidal infection substantiated by a positive cutaneous reaction was found in 2 of the younger group and lymphogranuloma venereum was found in another 2. Each gave a strongly positive reaction to the Frei test. There were 1 perianal and 2 paraurethral abscesses. Seven members of the group were drug addicts, each giving a history of scanty or no menstruation since forming the habit. Two patients were in the first trimester of pregnancy.

Every patient was classified as having chronic gonorrhea with the exception of 2 who were given absolute bed rest because their infections were acute. The only death in the series occurred from other causes six weeks after release from the hospital. Five patients having Bartholin abscesses were kept under observation

intervals on the chart devised by Rogers Deakin in his study of the treatment of gonorrhea in the male. Information contained in the accompanying tables is the result of an analysis of these records.

Table 1 refers to the first series of cases in which the sulfathiazole-beta-lactose therapy was used. All smears and cultures taken during the first week were positive, whereas during the third week positive laboratory examinations were obtained in only 4 (4.4 per cent) cases, each of which was considered a recurrence and therefore was subjected to another course of treatment. From the sixth to the fifteenth week all laboratory examinations were negative. During the fifteenth week positive cultures were obtained in 3 cases which had been pronounced clinical cures, since they had fulfilled the aforementioned criteria. However, the possibility of reinfection was established before they were listed as new cases. All smears and cultures in those followed for longer periods of time were negative.

Whenever a patient failed to return to the clinic for weekly follow-up examinations an arrest order was issued and she was brought in by the police, unless she had left the city. This accounted for the fact that it was possible to have 47 per cent of the patients under follow-up observation at the end of the twelfth week and 41 per cent of them at the end of the thirty-sixth week.

Eighty-six and six-tenths per cent of those under observation at the end of the fifteenth week were considered clinical cures, while all patients under observation at the end of the twenty-fourth week were considered clinical cures.

Table 2 shows results of treatment with sulfathiazole alone. All smears and cultures were positive at the end of the first week; positive results were obtained in only 2 (2.1 per cent) cases during the second week; after the third week all laboratory examinations were negative. Forty-seven per cent of this group of cases were under observation at the end of the twelfth week, and weekly smears and cultures were still being taken in 46 per cent of them thirty-six weeks after admission to the hospital. Ninety-seven and five-tenths per cent of these cases were pronounced "clinical cures" at the end of the fifteenth week and were still considered as such after a period of nine months had elapsed.

After a detailed analysis of these two groups it was obvious that local beta-lactose therapy had not been a factor in their treatment. For this reason the 194 cases have been summarized as a composite group (table 3) and may be recapitulated as follows: Smears and cultures were positive in 6 cases during the third week and in only 1 case at the end of the sixth week. The positive results obtained in three cases during the fifteenth week have been previously explained. Forty-five and four-tenths per cent of the cases were still under observation at the end of the twelfth week, while 41.7 per cent of the entire 194 cases were still being observed at the end of the thirty-sixth week.

Ninety-one and two-tenths per cent of the total number of patients under observation at the end of the "quarantine parole" period (twelve weeks) were considered "clinical cures," having completed prescribed treatment and giving negative results. By the end of the twenty-fourth week all patients under observation were "clinically cured." The results are presented graphically in the accompanying chart.

Results of treatment of total number of patients under observation at end of "quarantine parole" period. Solid line indicates positive smear or culture; broken line, lapse in attendance or closed without proof of cure; dots and lines, actual percentage of patients cured; dots and dashes, percentage of total number of patients cured.

for from ten days to three weeks, but in no instance were positive smears or cultures obtained from any part of the genital tract; therefore they are not included in this report. Twenty-one per cent of the patients had been subjected to operations for some type of pelvic inflammation. Thirty-five per cent had had at least one full term pregnancy, 1 patient having been delivered nine times. Twenty-six per cent admitted one or more induced abortions, the greatest number being seven by a 23 year old white girl.

Forty-five per cent of the patients had gonorrheal infection of the cervix alone; 43 per cent had both cervical and urethral infections, while the remaining 12 per cent had infections only in the urethra.

ANALYSIS OF RESULTS

Special forms were prepared for recording all information pertinent to this study. In general, the plan suggested by Deakin and his associates¹⁶ was used. The progress in each case was recorded at weekly

16. Deakin, R.; Wortman, M. S., and Lawrence, J. V.: Medical and Social Research in Gonorrhea, Ven. Dis. Inform. 21:255 (Aug.) 1940.

SUMMARY AND CONCLUSIONS

1. The object of this investigation has been to ascertain the efficacy of sulfathiazole in the treatment of gonococcal infections in women. One hundred and ninety-four hospitalized patients were subjected to a carefully controlled study. Two methods of treatment were employed, one consisting of the oral administration of 60 grains of sulfathiazole daily for five days and a vaginal suppository containing beta-lactose and boric acid. The suppository was given once a day for twelve consecutive days. The second method of treatment consisted of the same dose of sulfathiazole given without the beta-lactose.

2. Every patient showing clinical evidence of a gonococcal infection that could be confirmed by laboratory examination was isolated for a period of at least two weeks in a special unit of the St. Louis City Hospital. Special forms for recording all information pertinent to this study were employed.

3. Toxic manifestations were noted in 13 (6.7 per cent) cases and were sufficiently severe in 2 of them to necessitate termination of treatment. The most pronounced reaction was in the form of a painful urticarial rash in 1 case, while uncontrollable nausea and vomiting developed in a second. All cutaneous manifestations disappeared within seventy-two hours after administration of the drug was discontinued. Nausea and vomiting ceased within twenty-four hours after medication was stopped. In 7 cases there were mild nausea and malaise which were relieved by the administration of $7\frac{1}{2}$ grains of sodium bicarbonate for each dose of sulfathiazole. Mild fever reactions associated with chilly sensations and nausea were observed in 3 cases, all of which were relieved with sodium bicarbonate. In every case in which it was necessary to discontinue treatment reactions developed after the second course of medication was started.

4. One death in the series occurred six weeks after release from the hospital. This patient, a drug addict, had syphilis and acute malaria in addition to a gonococcal infection. Bartholin's abscess did not occur in this series.

5. Every case was classified as chronic gonorrhea with the exception of 2 in which there was an acute inflammation of the cervix, urethra and both adnexae associated with a severe febrile reaction. The cases classified as chronic gonorrhea presented no symptoms. This is in contradistinction to those classifications wherein the mere finding of a positive slide or culture warrants a diagnosis of acute gonorrhea.

6. Forty-five per cent of the patients had a gonorrheal infection of the cervix alone. In 12 per cent only the urethra was involved, while 43 per cent had both cervical and urethral infections. Every patient in whom the pelvic adnexae were present showed some type of chronic inflammatory condition.

7. A detailed analysis of the two groups of patients revealed that beta-lactose therapy had no influence on the treatment of gonococcal infection. Ninety-one and two-tenths per cent of the total number of patients under observation at the end of the "quarantine parole" period (twelve weeks) were considered "clinical cures." It may therefore be assumed that sulfathiazole in the treatment of gonococcal infections in the female is highly effective in a great majority of cases.

634 North Grand Avenue—4500 Olive Street—48 Municipal Courts Building.

ABSTRACT OF DISCUSSION

DR. WILLIAM H. VOGT, St. Louis: The authors have studied 194 cases of gonorrheal infection of the female and their results are most encouraging. The fact that these patients were hospitalized under a city ordinance and therefore had no opportunity for sexual relations during the course of treatment and also no chance of reinfection undoubtedly played an important part in obtaining the rapid cures. As I understand it, this report deals entirely with gonorrheal infections below the internal os. I wonder whether the authors have had any experience with this drug in the infection higher up in the pelvis. If equally good results can be obtained from this form of treatment in gonorrheal inflammation of the pelvis where it so often becomes necessary to sacrifice tubes and ovaries, the drug is truly to be considered a valuable addition to our armamentarium. The most serious complication in this group seems to have been a severe painful urticaria in 1 case of pregnancy associated with gonorrhea and 1 milder case of urticaria. All the other complications were mild nausea and malaise. Certainly one cannot criticize the drug on that basis. Serious conditions such as sulfhemoglobinemia, agranulocytosis and hemolytic anemia did not occur. No mention, however, was made of the need for the determination of blood concentration levels, and I am wondering whether these investigators did not think that this was necessary. In certain diseases associated with a high mortality and for which there is no reliable therapy, one may be justified in administering this drug in spite of some inherent risk and lack of facilities for determining the blood concentration. In less serious cases, however, such as gonorrheal infection, greater caution should be exercised in its use. I noticed that a discussion of the failure was omitted and I should be glad to have Dr. Fletcher say just what his plan of treatment has been in those obstinate forms of infection.

DR. WILLIAM BICKERS, Richmond, Va.: I am sorry but I must disagree with the speaker. In the last year I have accumulated a report on 50 acute cases of gonorrhea in women. Each alternate 1 was treated with sulfathiazole. At the end of the treatment period (and the treatments were well controlled by smears and the like) I myself evaluated each case, not knowing at the time of examination which patient had received sulfathiazole and which I had not. The conclusion is that we were not able by reviewing the histories of the patients, that is as to time when the smears became negative, the disappearance of dysuria, the absence of complications, the loss of days from work, and all of the other criteria by which we estimate the cure of gonorrhea in women, to make any distinction between the group treated by sulfathiazole and those that were not.

DR. PAUL F. FLETCHER, St. Louis: In answer to Dr. Vogt's question relative to treatment in obstinate cases, we found persistent foci of infection in the urethra and in the cervix in 8 cases. In 2, conization of the cervix was necessary. In 6, destruction of Skene's ducts with an electric cautery was employed. Those were the only obstinate cases in the series. Two cases showed inflammatory reaction. In each of them there was an acute or subacute bilateral salpingitis. The patients were deliberately subjected to the same course of treatment and by the time they left the hospital, within two weeks, all pelvic findings were essentially negative. With regard to Dr. Deakin's question relative to a method of controlling prostitutes after they are released from the hospital, two methods are being tried whereby they might be more effectively controlled, but time will not permit going into that now. In reference to the comments of my second discussor, I should like to say again that every 1 of these patients was a prostitute. All except 2 cases had to be classified as chronic gonorrhea. There is no question that close supervision and hospitalization were important factors. In contrast to this group, we have records of some 300 prostitutes who were treated with sulfanilamide and local therapy. By comparing the two groups of patients, the figures and facts speak for themselves. Our impressions and conclusions are based strictly and carefully on these facts. That is why we think sulfathiazole is effective in the treatment of gonorrhea in women in a rather high percentage of cases.

TRAUMATIC CHANGES IN THE RETINA, CHOROID, NERVE HEAD AND VITREOUS

ARTHUR J. BEDELL, M.D., D.Sc., LL.D.
ALBANY, N. Y.

Ocular tragedies are increasing in industry, in the home, in the school and in travel; so there is need for a review of the traumatic changes in the fundus and their differentiation from the nontraumatic. The application of facts learned in private practice is of immense practical value in times of stress, for it enables the alert physician to interpret the signs of early damage as well as to appraise correctly the end results.

The dominant signs of ocular injuries are hemorrhage, edema, ischemia and destruction of tissue. Their amount, location and extent provide the unpredictable elements.

A foreign body may strike the eye with varying force and from various angles. There is no accepted, dogmatic rule for determining the resulting changes in the fundus, but Lagrange, in his monumental sketchbook, presented conclusions well substantiated by his drawings and for certain war injuries laid the foundation for future advances.

In this clinical review an attempt is made to present the alterations in the fundus so clearly that the ophthalmoscopic patterns will become living designs.

Whenever a person has an accident to the eyes or the head he should be examined by one competent by training and a continuous experience to render an opinion. It must be understood that many injuries produce immediate, visible changes while with others the alterations are delayed and reexaminations are therefore imperative.

It will be shown that holes in the macula can result from injury, from inflammation of the uveal tract or from disturbance of the retinal circulation. Therefore, when one or more of these agents are present great care must be exercised to evaluate properly the effect of trauma.

TRAUMATIC HOLE

The traumatic hole at the retina is unilateral, except on rare occasions when both eyes are injured. This is a fundamental concept of the traumatic hole. The hole varies greatly in size, from $\frac{1}{6}$ to at least 2 disk diameters. The border may be a uniform gray, speckled with white spots, a few isolated dots, scattered pigmentary collections or thick gray tags. The crater ranges from a shallow excavation to a deep punched-out hole. The floor, or base, of the crater varies from dark red to pale pink and from a uniform granular appearance to one presenting dark ridges of irregular pigmentation, dense almost uniform sheets of pigment or scattered overlying white spots or films, or combinations of these, so that the floor may be smooth or rough. Finally, there are circummacular changes, such as pigmentary deposits and absorptions or massive connective tissue circles. It is therefore apparent that traumatic holes at the macula are not identical; further, it should be remembered that the macula does not always occupy the same position, for it may be either above or below the classic location.

If, then, the traumatic hole is visualized as a more or less sharply outlined red macular area with a distinct rim with tags on or about it, a physical differentiation must be made from a hole caused by circulatory or inflammatory changes, and, although no clearcut distinction is possible, the margin of error can be reduced to a minimum in this way. The appearance of every hole should be subjected to a critical analysis and then the possible causes considered.

The inflammatory hole is always unilateral unless there is bilateral inflammation. The evidence of involvement of the uveal tract: adhesions of the iris, vitreous opacities, complicated cataract and signs of choroidal and retinal disease, is always present. There are no significant differences in character between this hole and the others.

Circulatory holes are usually smaller than the traumatic ones and may be so small as to be overlooked because of the slight difference in color. They are always associated with changes in the retinal vessels ranging from little alterations to severe atheromas. They are bilateral, but one should not be misled if a hole is not present in both eyes the first time one examines a patient, for, although often circulatory holes are bilateral when first discovered, years may intervene before the second eye becomes involved. Delayed involvement of the second eye has been proved photographically in a sufficient number of cases to warrant emphasis, especially as the visual reduction is often little. The development of a circulatory hole from an overlying flat gray haze to cystic degeneration and finally to a clearcut hole has been observed. Often the rim is sloping. The crater may be shallow and scarcely measurable without a slit ophthalmoscope or a binocular one. Red-free light focused to transilluminate the macular area will often disclose the hole before it can be seen by the ordinary diffuse brilliant light. A delicate vitreous cloud may be so placed as to suggest the rim of a hole and may so obscure the border that the hole seems small.

In certain hypertensive patients without or with definite sclerosis a delicate, golden yellow, fine-meshed net forms about the uncovered macula, which stands out clearly as a more or less circular red disk. Neither this nor a dark macula should be mistaken for a hole. Careful ophthalmoscopic analysis will prevent these mistakes. A patient with hyperpiesia may receive a direct blow on the eye, and later a hole may develop in the macula. The relation of the blow to the development of the hole presents a medicolegal problem of considerable importance and calls for a careful consideration of the entire subject.

The hole that is found in detachment of the retina is curiously different. If the retina is in great folds the red hole seems to expand, contract and change its size every time the waving sheet moves. At one instant it is round, at another oval and at another a mere slit. When the retina is thick, gray and far displaced from the choroid the difference in level is striking and the dark crater is vivid against the whitish gray retina.

When the macula is involved after an operation or in a flat detachment it is usual to find many small, slightly elevated, light-reflecting cysts or the retina may be honeycombed throughout the entire region. There is no difficulty in distinguishing this kind of macular hole from the others, and whether it should be considered traumatic must be determined after the cause of the detachment is decided.

Before I leave the discussion of holes, it is necessary to mention the small one found in children with amblyopia and the clearly outlined hole in patients with glaucoma.

The macular hole is common and is seen far more frequently than published reports indicate.

RUPTURE OF CHOROID

Rupture of the choroid may be completely overshadowed by a hemorrhage, an exudate, edema or all three, so that no suggestion of an underlying tear is evident for several days. In the least complicated form there is an isolated yellow-gray swelling without hemorrhage. As the swelling disappears a yellowish band becomes apparent, usually more or less concentric with the disk, often to the temporal side but not rarely to the nasal. Ruptures may be single or multiple, more or less parallel to each other, angular, horizontal or stellate.

The most extensive tears follow severe direct blows which cause choroidal and retinal bleeding and detachment of the retina. The usual outcome is restoration of the retina to its former position, and if the rent does not involve the macular region, serviceable, functional recovery. The tear may leave areas of retinal and choroidal atrophy, or the separated yellow bands may become dense fibrous plaques. The color of the rupture depends on the time which has elapsed between injury and first examination. Early after injury the rupture is yellowish pink, with an indefinable margin, while later it is white, with sharp edges. Some cases have been reported in which pigmentation was said to be present immediately after an injury. Considered from a practical standpoint the reports cannot pass unchallenged, because the immediate presence of pigmentation is inconceivable, and pigmentation is of considerable value in the medicolegal determination of the time factor. Such unconfirmed statements are unjustified.

A rupture may shrink, remain stationary or even enlarge. Every case is instructive and of permanent value to the clinician who records the changes by means of photographs, for the patterns are often complicated in outline and surface, so that verbal descriptions are unsatisfactory. When a rupture of the choroid is combined with pigmentary degeneration, it is fair to assume that both have been caused by an injury.

Traumatic rupture of the choroid must be differentiated from the spontaneous choroidal tears which occupy the macular and paramacular regions in persons with high myopia. The refractive error, the angular rents (often with intact choroidal vessels either on the base or along the side of the deepest portion) and the uninterrupted state of the retinal vessels as they cross over the gaps are pathognomonic and are sufficient to exclude the diagnosis of a traumatic lesion.

Another confusing picture is that caused by tuberculous infiltrations, in which the pigmentation and elevation of portions of the center of each scar, with a superficial film over it, such as I first described in 1929 in a photographic exhibit on choroiditis, make the classification possible.

RUPTURE OF THE RETINA

Rupture of the retina is seldom diagnosed, for two reasons: It is difficult to see, and it is rare. Occasionally one finds a delicate interrupted superficial break in the retina after the traumatic edema has sub-

sided. The break is only slightly less pink than the rest of the fundus, the pigmentation is limited and vision often is unimpaired. Most often the tear is a horizontal line in the macular area which shows little or no tendency to close.

BERLIN'S EDEMA

The severe, acute macular edema first well described by Berlin causes transitory blindness when it is sufficiently great to blanch the retina in a more or less circumscribed macular area. Occasionally the pallor assumes the intensity of an embolic closure; more often there is a faint bloody effusion which gives a reddish or yellowish tinge to the swelling. When this is extreme it causes an elevation of the macula and a central scotoma. Occasionally there are collections of fine granular pigment.

EMBOLISM OF CENTRAL RETINAL ARTERY

Sudden loss of vision from embolism of the central retinal artery, with all its classic signs and symptoms, has been observed to follow immediately a forcible blow on the eye.

CHOROIDAL HEMORRHAGE

A direct compression of the globe may cause choroidal hemorrhage, which is seen as an oval or round bulging of the retina. If it is large the overlying retina is gray or almost milky white. When the borders are sharply outlined the retinal vessels curve over the surface. The hemorrhage may have a frayed edge, or the retina may be detached over the blood. There is no tendency for the blood to break through the retina, and the clinical course of absorption is one of decrease in size and thickness until the hemorrhage disappears. In some cases an outer granular ring shows where the blood has been, while in others the raised surface looks like melting snow. The hemorrhage frequently bulges over the borders of the disk as a smooth, glistening, dark red prominence.

GLAUCOMA

Increased ocular tension following a blow may pass unnoticed unless the elevation is great or rapid or both. In some cases hyphemia develops either immediately after the accident or some days later. If glaucoma is recognized and an operation performed early, the changes in the fundus are few, but if surgical intervention is delayed large deep retinal hemorrhages and choroidal extravasations are found, with a total glaucomatous excavation of the nerve.

TRAUMATIC ATROPHY OF THE OPTIC NERVE

Traumatic atrophy of the optic nerve has been described and recognized for many years. It may be partial or complete, sudden or gradual, and may be a complication of a severe injury of the head, a blow to the face or a seemingly trivial fall to which little attention is paid until the dimness of vision becomes apparent. This atrophy must be distinguished from that caused by the usual nontraumatic agents, which include syphilis, increased cranial pressure, the neuritides in general and embolism of the central retinal artery. The papilla may retain its normal color for a long time after an injury, although cases have been reported in which the nerve head turned white immediately after an accident.

AVULSION OF THE OPTIC NERVE

Avulsion of the optic nerve is most often the result of a gunshot wound when the bullet, as it passes through the skull, cuts one or both optic nerves. When the

nerve is completely severed the region of the papilla is a great white depression. Usually, a thick, white, elevated connective tissue band of variable width and excessive pigmentation surrounds the scar. When the nerve is partially detached from its insertion the amount of scar tissue makes it look like a deep glaucomatous excavation. White proliferating bands and depigmentation of the choroid similar to those of traumatic retinochoroiditis are often prominent.

The end results of total or partial avulsion are so striking that once seen they will always be remembered. Partial avulsion is the more difficult to diagnose.

CONGENITAL COLOBOMA

When congenital coloboma of the disk and the choroid is associated with a marginal zone of depigmentation, care must be taken to avoid calling it a traumatic lesion.

RETINITIS PROLIFERANS

Retinitis proliferans may follow a penetrating wound and show as white strands adherent to the disk and at the points of contact in the retina. The bands may be thick and smooth, with many vessels on them, or delicate and avascular. They may be in any portion of the fundus but seem to have a predilection for the peripapillary region. In some cases the bands of proliferation are dark, almost black, beneath more superficial, lighter webs. They are distinguished from the retinitis proliferans of tuberculosis by their isolation and by the tendency to remain stationary. In tuberculosis recurrences are not infrequent. In the retinitis proliferans of diabetes the sheets are denser and more vascular, for the vessels are in many layers, while in hypertension and syphilis changes in the retinal vessels are always present.

TRAUMATIC MACULAR PIGMENTATION

Pigmentary changes in the macula may be linear or spotlike. The fovea may be brownish yellow, in contrast to the pale red fundus. The changes may follow the extraction of an intraocular foreign body and may be a primary retinal change or a secondary terminal effect. Macular retinal hemorrhage, juvenile macular choroiditis, retinochoroiditis and disciform degeneration may suggest by their location and shape the traumatic changes. Careful inspection will distinguish one from the other.

TRAUMATIC RETINOCHOROIDITIS

Traumatic retinochoroiditis with permanent visual loss may appear under several more or less distinct forms. The areas may be widespread and may cause extensive destruction, for they follow either direct contusion or compression of the globe. Immediately after the accident the retina is white and swollen, with a few hemorrhages on its surface. The pigmentation does not become apparent until the swelling has disappeared. In unusually bad cases there is rupture of the choroid and detachment of the retina. It takes several weeks for a severe lesion to become resolved. Traumatic retinochoroiditis is differentiated from areolar sclerosis by two facts: First, in sclerosis the border is sharp and clearly separates the diseased from the uninvolved portions of the fundus, whereas in traumatic retinochoroiditis the border may be pigmented in only a part of its circumference and usually blends with the surrounding retina. Second, in sclerosis the floor almost always consists of grossly sclerosed choroidal vessels

with or without scattered pigmentation, and sometimes in cases of long standing the vessels are reduced in number, while in traumatic retinochoroiditis the choroidal vessels are not sclerosed and, as a matter of fact, are notably reduced in size and number. In non-traumatic retinochoroiditis of the exudative type thick white scars with dense pigmentations are often encountered.

PENETRATING WOUNDS

Penetrating wounds of the globe may produce localized damage at the site of puncture; these include pigmentation, scars and proliferation. When the eyeball is penetrated from the rear, unusual rounded tubular membranes often project through the distended and stretched coats like fingers through a dark, heavy woolen cloth. Anterior, or lateral, perforations are much more common, and if the wound is back of the lens and is not infected, a scar is found, varying from a single line to a wide band. The latter leads to total detachment of the retina.

CHANGES DUE TO FOREIGN BODIES

Changes caused by intraocular foreign bodies form a class of their own. When a BB shot enters the globe, it may cause considerable destruction of the retina and choroid, or after striking the retina it may settle in one of the lower quadrants. When it does, if the patient is placed on his side the force of gravity will cause the shot to become lodged in the sclera and produce a secondary inflammatory reaction. As soon as this occurs an incision over the most prominent point will enable the surgeon to remove the shot with little added trauma.

If the foreign body is steel or iron, it may be possible to see it in the vitreous, more commonly in the retina or, when it penetrates the retina, in the choroid or the sclera. Immediately after the injury the foreign body may be covered with blood, and as the hemorrhage becomes absorbed organization of exudate may take place. If the metal is retained long siderosis develops. The degree of reaction in the fundus varies with the size of the body, the force of contact and whether the object was infected.

When the foreign body is copper it causes the characteristic retinal change of small discrete paramacular yellow spots. These may become less evident, but if the foreign body cannot be removed the reaction increases and the deposits become larger.

Wood splinters provoke a severe exudative inflammation, while glass induces little reaction.

It is obviously impossible to do more than suggest some of the changes in a paper of this size. When the foreign body is lodged in the sclera the resulting hole in the retina may lead to detachment, but if the foreign body is removed and the detachment treated the results are favorable. It must not be forgotten that a foreign body may enter one side of the eye, strike the retina and rebound to the other and produce some unusual scars.

DETACHMENT

Only a summary statement is made regarding traumatic retinal detachments, for there are as yet no absolute pathognomonic signs which distinguish those of spontaneous origin, such as occur in the myope, the gravid woman or the person with a malignant neoplasm of the uveal tract, from those ascribed to physical strain.

Isolated perimacular retinal edema and preretinal edema have been called detachment. Attention to the distinguishing sharp reflex lines from the retina in the former and from the vitreous in the latter are important aids in differentiation. Furthermore, the clinical course is entirely different, for with detachment there is usually progression, whereas with retinal edema the area may enlarge but soon contracts, while with preretinal edema the dome of the swelling expands rapidly, then flattens and disappears. Shallow, flat, finger rolls of detachment are easy to differentiate from the bands caused by folds in the retina because of the irregularity of direction and size as well as the gray color, for folds are more often streaklike and of a yellow tinge. Large globus detachments are easily recognized as they wave on motion of the eyeball, for they have wrinkles in the surface and dull reflexless retinal vessels. The literature is replete with details concerning retinal detachments, so that it is not included.

The retinal vessels may pass over great rents in the retina without change in direction and often are so taut that they indent the lips of the tear, or they may be torn, causing hemorrhage and eventually changes in their caliber.

CHOKED DISK

• The diagnostic value of increasing edema of the disk has been previously stressed, for rising intracranial pressure must be reduced or serious progressive damage to the optic nerves will follow. Again I urge more care and more frequent study of the fundi in every case of fracture of the skull.

TRAUMATIC ARACHNOIDITIS

In cases of traumatic arachnoiditis a swollen papilla with a crown of blood is sufficiently alarming to demand constant observation. If the papilledema does not quickly subside, surgical measures should be employed. In this connection caution is advised against the promiscuous injection of air for encephalograms, for the subsequent elevation of intracranial pressure may cause papilledema, with a retinal hemorrhage.

A striking confirmation of the fact brought out by Parker's experiments, that papilledema first occurs in the eye with the lower ocular tension, may be observed in the case of a large scleral cut which heals with separated scleral lips and a swollen disk.

Finally, attention is focused on pulsating exophthalmos, either spontaneous or traumatic. Frequently diplopia is the first symptom. Examination discloses the bruit heard over the head, and as the blood vessels dilate the eye bulges forward, the conjunctival vessels become full, the vessels of the lid become tortuous and enlarged and the great orbital vessels form immense blood channels. The fundus is then congested, and the vessels are usually a carmine red and the pulsations forcible. A sign of some prognostic value is the persistence of a definite fundus congestion after fracture of the skull.

SUMMARY

The fundus patterns made by trauma are both numerous and destructive. Those resulting from loss of tissue are holes in the retina and ruptures of the choroid.

Those from disturbed circulation include holes, macular pigmentations, chorioretinitis and embolisms.

The special inflammatory reactions are retinitis proliferans and scars.

Actual cutting includes avulsion of the optic nerve, and the result of pressure on the nerve either in the orbit, the bony canal or the brain is papilledema or atrophy.

The nontraumatic changes are contrasted with those caused by injury.

CONCLUSIONS

An ophthalmoscopic examination is imperative in every case of injury to the head or the eye.

Meticulous care should be taken in the original description of each case, special notations being made regarding the time interval, the type of injury and, if possible, the direction of the force and the end result. Obviously, no report is complete without a clear photograph.

Every patient presents a complicated individual condition which demands an exact diagnosis based on a comprehensive knowledge of the possibilities.

The aim of all examinations is to establish whether the changes are traumatic or nontraumatic, for the maintenance of the delicate balance of justice must rest on the sure foundation of knowledge, not on bias.

ABSTRACT OF DISCUSSION

DR. PARKER HEATH, Detroit: As Dr. Bedell has pointed out, differentiation of trauma from other similar lesions is becoming increasingly important with the spread of compensation laws. The point made in the detachment of the retina of differences in color in the background in patches is important. In an organ whose tissues have such concentrated importance as in the eye, not infrequently the initial lesion is less important than the subsequent inflammatory repair. The effect of trauma to the eye is poorly classified in literature. There would seem to be three main approaches to the subject: 1. Clinical study with case notes, repeating these studies so that the whole course of the disease can be noted. This study is of immense value and is the method chiefly emphasized by those reporting their studies in atlas and in literature. An advance in this field will be made by more correlation with the clinicians, as shown by the studies of Wagener, a cheaper fundus camera and color photography with a film which will not fade. An example of case study, though incomplete, is that found in Lagrange's book describing war injuries, wherein he attempts to show the effect of missiles striking near the eye and taking a certain course; also the results from exposure to explosive forces. 2. The second form of study is that of correlating physiology and pathology with the changes in the eyes, using the same methods. An attempt along this line is a correlation of histopathology in the atlas of Guist, and a valuable correlation of histology and clinical data is that of Temple University. This attractive field has scarcely begun to be explored, although the source of material is as common as the general autopsies. The difficulty here is the effort involved—especially the studies of the eye before death. 3. The third field, still less explored, is that concerning the changes in the fundi from trauma in experimental studies. The possibilities here are great for adding valuable knowledge. I would close with the plea that, in addition to such fine clinical studies as Dr. Bedell's, other correlated ophthalmoscopic findings with pathology and physiology of the eye and also more experimental studies be undertaken in the field of ocular trauma.

DR. MORRIS DAVIDSON, New York: There are two aspects to the presentation by Dr. Bedell: The first is the place of fundus photography in ophthalmology. The splendid series of photographs leaves no doubt as to its value for teaching purposes. Photographic documentation for medicolegal purposes is also of great advantage. There are apparent limitations. One is the small area a fundus camera takes in. Furthermore, in the whole series of slides there wasn't one peripheral fundus

lesion. Evidently the camera finds it difficult to pick up the peripheral fundus lesion. The fundus is a large area, and it is misleading for the student to see the small posterior pole of the fundus instead of the whole fundus. Every ophthalmologist should practice some method of graphic recording of his observations. Every one of us makes some kind of a crude sketch of an observation. The available record forms have never been satisfactory, and out of my own needs I have evolved a topographic chart for recording eye injuries for the New York State Department of Labor. My colleague Dr. Goldberg, at the New York State Department of Labor, and I have tested ourselves as to our ability to identify a particular fundus lesion etiologically, without the benefit of a complete eye examination, including a slit lamp study of the anterior segment, and without the help of the concept of the anterior segment contusion syndrome. We were greatly disappointed in our diagnostic skill. It is in contusions where most of the controversies as to the traumatic or nontraumatic etiology of eye lesions occur. I should like to call attention to the reality and value of this syndrome. It consists in a train of lesions, anatomically related, in the pupils, iris, lens, vitreous and fundus periphery. Not every contusion presents all lesions, but two or more are found in every case.

DR. M. M. CULLOM, Nashville, Tenn.: I wish to express my gratitude to Dr. Bedell for his great work on the fundus and the beautiful way he has pictured it. I also want to ask his opinion, and yours, about a medicolegal case. A year ago a man came into the office with a history that while at work he and several of his co-workers were lifting a heavy timber. One of the men slipped and threw almost the whole weight of the timber on him, causing him to make a great effort to hold it up. In a few minutes he said "I can't see out of my right eye." On examination two days later he presented a picture of an embolus in the central artery. I gave it as my opinion that it was the strain that brought about the embolus. I was called to court to testify in this case. I consulted all the books I had in the office, and not one of them gave such a cause for embolus. The lawyer asked me whether I knew any authority that backed up my opinion. I couldn't answer that question very well. However, I found later that Adams Frost gives strain as a cause for embolism of the central artery. Dr. Bedell brought out the question of trauma in connection with embolism of the central artery. A week ago a man of 55 came in with a perfect picture of embolus. His history was that he had been on a spree for a week and had gone to the hospital to sober up. I had the man carefully examined and every test that we made was negative. His heart and blood vessels and tension were normal. The urinalysis was normal and Wassermann reaction was negative. There was nothing we could find that might account for it.

DR. ARTHUR J. BEDELL, Albany, N. Y.: I wish to thank Dr. Heath for reading the paper carefully, and for his timely discussion. It is very important that we keep in mind the suggestions made by Dr. Heath in relation to the study of clinical material, and particularly the correlation of the physiologic and pathologic findings. If we are to make experimental studies, then the results should be photographed and interpreted by a competent examiner. I appreciate Dr. Davidson's discussion, but as the subject is only fundus lesions I will not speak about the anterior segment syndrome. Photographs are made most often of central lesions, but that does not mean that we cannot take pictures of the fundus periphery. Dr. Davidson's diagram showed only the central field. Dr. Cullom reports an interesting clinical case. The patient lifted a heavy weight and immediately went blind. I believe Dr. Cullom can honestly and fairly go before the court and say that the blindness was caused by the exertion of lifting the great weight. In closing I will quote one paragraph, for it is very vital: "The aim of all examination is to establish the truth as to whether the changes are traumatic or nontraumatic, for the maintenance of the delicate balance of justice must rest on the sure foundation of knowledge, not bias."

RADIATION THERAPY IN CARCINOMA OF THE LUNG

WILLIAM V. TENZEL, M.D.
NEW YORK

Radiation therapy for primary carcinoma of the lung has not been effective as a curative agent. However, its usefulness in palliation and in prolonging life should not be overlooked. Even in these spheres the value of radiation therapy has been challenged. Overholt¹ of the Lahey Clinic believes that radiotherapy shortens the life of patients with cancer of the lung; Portmann² of the Cleveland Clinic states that radiotherapy may result in symptomatic relief but not in prolongation of life, while Craver³ of the Memorial Hospital, on the basis of 178 cases, reports that radiation therapy gives symptomatic relief and prolongs life.

* Three patients were excluded—2 had pneumonectomies and the third an early lesion giving no symptoms and accidentally discovered at autopsy.

The present report based on an analysis of 192 treated and untreated primary carcinomas of the lung which had been examined post mortem at Montefiore Hospital from 1921 to 1939, demonstrates the value of radiation therapy in prolonging life. It was felt that autopsy material permitted a more accurate estimate of the influence of radiotherapy on the duration of life, especially as a comparison was possible between treated and untreated patients.

MICROSCOPIC CLASSIFICATION

The cases were divided into three groups according to the microscopic character of the tumor. Of the 192, 50 were classified as adenocarcinomas, 105 as epidermoid carcinomas and 37 as anaplastic carcinomas (table 1). The adenocarcinomas included types forming mucus (fig. 1), and those not forming mucus (fig. 2). The epidermoid carcinomas were either the

typical squamous cell keratinizing carcinoma (fig. 3) or the nonkeratinizing or basal cell type (fig. 4). The anaplastic group consisted of the spindle cell variety (fig. 5) and the round cell type (fig. 6). Occasionally the classification was difficult because two or more

(table 3). The survival period was longest in epidermoid carcinoma: sixteen and one-half months for the irradiated and eleven months for the nonirradiated patient. It was shortest in adenocarcinoma: eleven months for the irradiated group and seven and one-half months for the nonirradiated group.

The effectiveness of radiotherapy in prolonging life is further illustrated by a comparison between the number of treated and the number of untreated patients

183		68	15.0	121	10.0

DURATION OF DISEASE WITH AND WITHOUT IRRADIATION

A comparison was made between the irradiated and the untreated patients. There were 121 untreated and 68 irradiated patients. In both the treated and the untreated patients an average period of five and one-half months elapsed between the onset of symptoms and the diagnosis, as seen in table 2. This period was somewhat longer for the epidermoid carcinoma.

The average duration of life from onset of symptoms to death for the irradiated patients was fifteen months and for those not given irradiation only ten months

Fig 2—Adenocarcinoma, nonmucus forming

THE RELATIONSHIP OF TUMOR DOSE TO SURVIVAL PERIOD

The voltage, target skin distance, filter, size and number of portals, dose and interval between treatments varied from case to case, depending on the extent of the lesion and the general condition of the patient. Since

there were so many variables, the treatment is best described by giving the total dose received by a definite point in the affected lung. An arbitrary point was chosen located 10 cm. from the anterior, posterior and

group the number of cases is too small to make a positive statement, but the results suggest the survival period increased with increasing dosage.

METASTASES AND INFECTION

The method of treatment and the end results were influenced by the condition of the patient and the pres-

survival period in cases in which roentgen treatment was given. As the tumor dose increases there is a definite and progressive increase in the survival period. When the tumor dose was 1,000 r or less, the survival period was about the same as in the untreated group. As the tumor dose was increased, the average survival period was lengthened. With from 1,000 to 2,000 r, the survival period was eleven and one-half months; with from 2,000 to 3,000 r, twelve months; with from 3,000 to 4,000 r, thirteen months; with from 4,000 to 5,000 r, fourteen months, and with from 5,000 to 6,000 r, twenty-two months (table 5). For each dosage

Fig. 4.—Squamous cell carcinoma, nonkeratinizing.

ence of distant metastases. As seen from tables 6, 7 and 8, carcinoma of the lung gives rise to widespread metastases to the skeletal system as well as to all other parts of the body. There was relatively only a small

number of patients in whom the disease remained local. At autopsy 92 per cent of the adenocarcinomas and anaplastic carcinomas had distant metastases. This would indicate that there is little chance for successful

advanced. Since the general health of the patients is poor, they are often unable to withstand a course of vigorous radiotherapy. Some degree of palliation for a period of from one to thirteen months was obtained by 17 of the 38 patients who received their entire treatment at Montefiore Hospital. The symptoms most frequently relieved were cough, expectoration, hemoptysis and pain in the chest.

bronchial growth frequently occluding the bronchus early, with resultant atelectasis, retention of secretions and infection. The tumor even in the very early stages has a tendency to undergo central necrosis and liquefaction. At autopsy, abscess of the lung was present in about 50 per cent of the cases of epidermoid carcinoma, whereas in the adenocarcinoma group there was only 9 per cent, and in the anaplastic carcinoma group 18 per cent.

SYMPTOMATIC RELIEF

Carcinoma of the lung is an insidious disease, and when the diagnosis is made the disease is usually

mortem at Montefiore Hospital was made to determine the effect of radiation therapy.

2. The tumors were classified histologically as epidermoid, adenocarcinoma and anaplastic carcinoma.

3. In one third of the cases of epidermoid carcinoma there were no distant metastases, while in those of adenocarcinoma and anaplastic carcinoma there were distant metastases in 92 per cent of the cases.

4. The survival period of irradiated patients was on an average five months longer than that of patients not so treated.

5. Twice as many irradiated as nonirradiated patients survived more than one year.

6. The greater the tumor dose delivered within specified limits, the longer was the survival period.

7. Symptomatic relief was obtained by 45 per cent of the patients treated at Montefiore Hospital.

EXPERIMENTAL EVIDENCE FOR HISTAMINE RELEASE IN ALLERGY

GERHARD KATZ, M.D.

AND

STANLEY COHEN, M.D.

NEW ORLEANS

It has long been assumed that histamine plays a role in allergic reactions and that it may in part be responsible for many of the clinical symptoms in allergy. The actual experimental evidence for this hypothesis, however, is meager and circumstantial. It is, on the whole, based on the similarity between the allergic and the histamine cutaneous reactions and on some similarities between allergic attacks and the systemic effects of histamine injections. To our knowledge, the presence of a histamine-like substance after application of allergen to tissues from sensitized patients has not been demonstrated convincingly.

An experimental approach to the study of histamine release in allergy suggested itself from observations on anaphylaxis which one of us has made recently.² It was found that blood cells from sensitized animals released part of their histamine into the plasma when brought into contact in vitro with the antigen. Extensive experimentation has made it probable that the amount of histamine released from tissues goes, to a certain extent, parallel to the intensity of the functional disturbances of the animal in anaphylactic shock.³ It had seemed therefore justifiable to consider as a working hypothesis that the in vitro histamine release by blood cells from sensitized animals is an indicator of the degree of the animal's sensitization. This assumption was substantiated in experiments in which the degree of blood histamine release was correlated with the capacity of the animals to undergo shock. Since this method of producing in vitro shock of blood cells and determining the resulting histamine release is quali-

tatively and quantitatively accurate and dependable and allows one to experiment on one individual over unlimited periods of time without endangering life or disturbing the state of sensitization, an attempt was made to apply it to allergic patients.

EXPERIMENTAL OBSERVATIONS

When venous blood from a nonallergic individual was incubated with extract of allergen (giant ragweed, timothy or house dust) at 37 C. for fifteen minutes, no change in plasma histamine was observed. When, however, blood from a patient sensitive to the allergen was subjected to the same procedure, the plasma histamine level rose considerably. From 75 experiments on blood from 18 patients, the accompanying table shows some representative results. This reaction is apparently specific. Blood from a patient, for instance, who is clinically sensitive only to ragweed and not to timothy showed an increase in plasma histamine only on incubation with ragweed and not with timothy extract. The amounts of allergen used in these experiments were supramaximal; that is, they were kept higher than was necessary to effect the greatest possible plasma histamine rise. The source of the increased plasma histamine in this in vitro shock is the cells and not the plasma. Incubation of the sensitized plasma with the allergen left the histamine level unchanged.

Plasma Histamine Values After Incubation of Heparinized Blood with Locke's Solution ("Control") and Giant Ragweed Extract ("Shock") for Fifteen Minutes at 37 C.

No.	Condition of Patient	Date	Plasma Histamine in Micrograms of Base per Cubic Centimeter After Incubation of Blood with		
			Locke's Solution	Ragweed Extract	Increase
1	"Normal"; no evidence for allergy	1/29/41	0.013	0.015	15%
2	Ragweed and house dust allergy	3/24/41	0.020	0.032	60%
3	Ragweed and house dust allergy	10/28/40	0.019	0.051	168%
4	Ragweed allergy.....	3/ 7/41	0.004	0.036	650%
		10/ 9/40	0.050	0.14	189%
		10/22/40	0.013	0.040	259%
		4/28/41	0.005	0.050	900%
5	Ragweed allergy.....	2/ 9/41	0.003	0.030	900%
		2/14/41	0.014	0.040	186%
		3/ 3/41	0.017	0.030	76%

The ragweed extracts were free from detectable histamine. The volume of the solutions added to blood was 10 per cent of the sample. Usual over-all error of histamine estimation was ± 15 per cent.

According to our findings thus far, the histamine release from blood cells in the allergic in vitro shock varies greatly when a patient's blood is examined at different times. It seems to go parallel to the capability of the patient to have clinically manifest allergy. It does not regularly go parallel with the degree of response to the intradermal test.

COMMENT

This report is not concerned with studies of the role of histamine in different clinical allergic pictures. It is only intended to prove that, as far as blood cells are concerned, the cellular allergic reaction is histaminergic. The amounts of histamine released from blood cells on contact with the allergen could be large enough to be biologically significant in vivo. We may assume that at least at points of high concentrations of allergens, such as tissues of the respiratory or digestive tracts, the histamine released from blood cells

Aided by a grant from the John and Mary R. Markle Foundation (to G. K.). The authors were given invaluable technical assistance by Miss Marguerite Magee.

1. In this report the term "histamine" is used in preference to "histamine-like substance." It is a substance which has been extracted by the method of Barsoum and Gaddum (Code, C. F.: The Quantitative Estimation of Histamine in the Blood, *J. Physiol.* 89: 257 [April] 1937) and assayed biologically on the isolated atropinized guinea pig's ileum.

2. Katz, Gerhard: Histamine Release from Blood Cells in Anaphylaxis in Vitro, *Science* 91: 221 (March 1) 1940; The Role of Blood Cells in the Anaphylactic Histamine Release, Dragstedt, C. A.: The Relationship of Histamine to Anaphylaxis in the Rabbit, *Science* 91: 617 (June 28) 1940.

3. Code, C. F.: The Histamine Content of the Blood of Guinea Pigs and Dogs During Anaphylactic Shock, *Am. J. Physiol.* 127: 78 (Aug.) 1939. Ojers, G.; Holmes, C. A., and Dragstedt, C. A.: The Liver Histamine in Canine Anaphylaxis, *J. Pharmacol. & Exper. Therap.* 72: 30 (May) 1941. Katz, G.

circulating through these areas should, to a certain extent, contribute to some of the local tissue reactions. The possibility of remote action should also be kept in mind. It is conceivable that histamine is released systemically from circulating blood cells after they have come into contact with allergen at the allergic ports of entry. It should be pointed out that histamine is not necessarily the only active humoral principle which is released or formed in antigen-antibody reaction. In the anaphylactic *in vitro* shock of blood, for instance, one of us found at least one active substance appearing in the plasma, with chemical and biologic properties different from histamine.⁴

If one can accept the hypothesis that the *in vitro* histamine release from blood goes to a significant degree parallel to the extent to which the patient's tissues show allergic reactions in spontaneous or induced attacks, then one is offered the possibility of investigating, by this method, allergic states comparatively accurately in controlled experiments. As pointed out, our observations so far support this hypothesis.

Clinical Notes, Suggestions and New Instruments

THE RELATIVE EFFECTS OF SEVERAL SUBSTANCES IN MINIMIZING IRRITATION CAUSED BY ADHESIVE PLASTER

ROBERT F. LEGGE, M.D., OAKLAND, CALIF.

Feeling that the degree and amount of irritation produced by adhesive plaster might be minimized by attempting to protect the skin before its application with certain substances, I carried out the series of observations presented in this paper. Previously the investigation of this phenomenon had been directed chiefly toward an effort to determine the factors involved in its production. This was done, undoubtedly, with the object of removing from the plaster the irritants which caused the irritation. Apparently it is impossible to remove these irritants without reducing the effectiveness of the plaster so far as its adhesive properties are concerned.

Schwartz and Peck¹ in 1935 concluded as a result of their studies that the chief irritants were resins and smoke-cured wild rubber and that irritation was due partially to hypersensitivity to one of these ingredients. However, they also felt that some irritation resulted from maceration of the skin from application and removal of adherent material.

Grolnick² in 1936 concluded that specific sensitivity was present in only a small number of persons. In fact, only 2 such persons out of 275 tested were found. However, some irritation was noted in 1 out of 6 subjects. Further study by Grolnick in 1940³ seemed to prove in 48 subjects by means of the patch test that specific dermatitis was even less common and that a certain amount of nonspecific irritation could not be avoided.

Forty-six different persons were used for this study. The strappings were always of the lower part of the back, and the area strapped was approximately 7 inches by 15 inches. In each instance the area to be strapped was divided into four squares. One of these was not painted, for a control. The others were painted with compound tincture of benzoin, merthiolate and metaphen. The latter two substances were each in a 50 per cent alcohol, 10 per cent acetone solution, and they will subsequently be referred to as solutions A and B. In each

instance the strappings remained in place for one week, at which time the observations were made. The sites of the squares were varied, so that the square treated with benzoin, for instance, was at one observation in the middle of the field to be strapped and at another on the edge. The reactions of the skin were classified as normal, that is, without any evidence of reaction; erythematous irritation; pustular irritation; bleeding, and vesicles.

Seven of the 46 subjects, or 15.2 per cent, showed no reaction in any of the squares; 36, or 78.3 per cent, showed reaction in one or more of the squares, and 3, or 6.5 per cent, showed reaction in all four squares. The latter subjects may have represented instances of specific hypersensitivity. Since there were four squares on each person, 184 observations were represented. Of these, 106, or 57.6 per cent, were negative, while 78, or 42.4 per cent, showed some irritation. Of the squares showing no reaction 50, or 47.2 per cent, were on edges and 56, or 52.8 per cent, were in the middle, indicating perhaps that the edges were slightly more subject to tension trauma.

Table 1 shows the number of reactions in the squares treated with the three solutions and in those left untreated. From this it will be seen that the greatest number occurred in the untreated squares and that the least number occurred in those treated with solution A.

Table 2 shows the number and percentage of the different types of reactions observed.

Table 3 analyzes the method of treatment of the areas in the causation of each type of reaction. It will be seen that solution A produced the smallest number of irritation reactions. The greatest number of pustular irritations was seen in the squares treated with solution B.

SUMMARY AND CONCLUSIONS

It is felt that this series of observations shows definitely (1) that a certain amount of cutaneous irritation will be present under adhesive strapping; (2) that painting the skin before the adhesive is applied with any one of the three solutions

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary.

PHENYLMERCURIC COMPOUNDS

Phenylmercuric chloride and basic phenylmercuric nitrate were the first of the organic mercurial compounds of their type found to possess effective bacteriostatic and bactericidal activity against certain pathogenic micro-organisms. Evidence to indicate that other phenylmercuric salts are similarly effective suggests that the activity of such compounds is primarily attributable to the phenylmercuric ion. In general, phenylmercuric salts are highly dissociable in solutions to provide phenylmercuric ions, effective concentrations of which are dependent on the widely varying solubility of the salts employed. In acid, neutral or slightly alkaline solutions, chlorides, bromides, iodides and soaps react with phenylmercuric ion to precipitate a phenylmercuric salt. Phenylmercuric chloride is soluble only to the extent of 1 part in 20,000 of water, the bromide is still less soluble and the iodide is quite insoluble. For this reason the chloride has been supplanted by the more soluble basic phenylmercuric nitrate and other salts.

The phenylmercuric radical ($C_6H_5Hg^+$) is more stable in acid than in alkaline solutions of its salts. Aqueous solutions containing phenylmercuric ions, buffered with inorganic or organic acids, are fairly stable. In the presence of organic solvents the stability is lowered but is still relatively good. Because of the fact that buffered solutions of phenylmercuric salts are more stable and also less irritating to tissue than unbuffered solutions, the former are preferable for pharmaceutical purposes. In general, the buffered solutions are stainless, colorless, odorless, without action on rubber, do not react with the body proteins and are noncorrosive to the common metals other than aluminum, except as these properties may be influenced by the particular acid employed. Solutions of phenylmercuric salts may develop increasing amounts of mercuric and mercurous ions or free mercury, as the result of gradual decomposition of phenylmercuric ions.

There is evidence to indicate that phenylmercuric compounds are of comparatively high germicidal and inhibitory value against a variety of pathogenic bacteria and of relatively low toxicity to human tissue. As with the other types of organic mercurial antiseptics, however, they cannot be depended on to kill bacterial spores even after several hours' exposure. The presence of buffered solutions of phenylmercuric salts does not interfere with the precipitin reaction of human serum, the action of complement, the digestive action of pepsin and trypsin or the antigenic power of vaccine; serum proteins are not precipitated and blood is not hemolyzed. Despite their relatively low toxicity, phenylmercuric compounds may produce irritation, "burns" or poisoning in occasional individuals with undue sensitivity. The minimum lethal intravenous dose for rabbits of a 0.067 per cent (1:1,500) aqueous solution of basic phenylmercuric nitrate (buffered with 0.1 per cent boric acid) is 7 cc. per kilogram of body weight. Other evidence indicates that the minimum lethal oral dose for these animals is approximately three times the intravenous dose. The toxicity of solutions of this and other phenylmercuric salts may be expected to vary according to the concentration of phenylmercuric ions, the presence of organic solvents, the acid which is added as a buffer to render them stable and the degree of decomposition. The appearance of metallic mercury as a precipitate in solutions of phenylmercuric salts indicates extensive decomposition.

MERPHENYL NITRATE (BASIC).—Basic Phenylmercuric Nitrate.—A molecular compound of phenylmercuric nitrate and phenylmercuric hydroxide. $C_6H_5HgNO_3 \cdot C_6H_5HgOH$ (F. W. 634.4).

Actions and Uses.—Merphenyl nitrate (basic) is recognized for external use in solution or ointment as an antiseptic for the prophylactic and therapeutic disinfection of the skin, superficial abrasions, lacerations, wounds and infections.

Dosage.—For prophylactic disinfection of the intact skin and minor lesions the 1:1,500 aqueous buffered solutions may be applied full strength; for application to mucous membranes or for the application of wet dressings or continuous irrigation to

wounds, a 1:15,000 to 1:24,000 aqueous solution should be used (prepared by diluting the 1:1,500 buffered solution approximately ten to fifteen times with water). When used as a wet dressing, the 1:24,000 dilution should be prevented from becoming too concentrated, as the result of unavoidable evaporation, by the addition of about 0.5 per cent of sodium chloride. Approximately $\frac{1}{2}$ teaspoon of noniodized table salt to each pint of diluted solution is recommended. This amount of sodium chloride does not produce excessive precipitation. The full strength (1:1,500) solution should never be used to wet bandages or dressings. The 1:1,500 oxycholesterin base ointment may also be employed for the prophylactic disinfection of minor injuries or may be applied twice daily for the treatment of superficial infections.

Manufactured by the Hamilton Laboratories, Inc., Hamilton, Ohio U. S. patent 2,014,676 (Sept. 17, 1935, expires 1952). U. S. trademark 318,039.

Merphenyl Nitrate (Basic) Solution, 1:1,500.—An aqueous solution of basic phenylmercuric nitrate 0.067 per cent (1:1,500), with boric acid 0.1 per cent.

Merphenyl Nitrate (Basic) Ointment, 1:1,500.—A water in oil emulsion ($\frac{2}{3}$ aqueous, $\frac{1}{3}$ oil phase) of an oxycholesterin base containing basic phenylmercuric nitrate 0.067 per cent (1:1,500), with boric acid 0.1 per cent.

Basic phenylmercuric nitrate is an odorless, white, crystalline powder, which melts with decomposition between 175 and 185 C. (extremely pure specimens melt as high as 192 C.). It is soluble (1:200) in glycerin, slightly soluble (1:800) in alcohol and very slightly soluble (1:1,200) in water. Its apparent solubility in water is increased if nitric acid or alkalis are present. Aqueous solutions of basic phenylmercuric nitrate are incompatible with halides, which cause the precipitation of the nearly insoluble halide compounds; e. g., phenylmercuric chloride (C_6H_5HgCl). The pH of a 0.1 per cent aqueous solution of basic phenylmercuric nitrate is approximately 3.7.

Add 3 cc of sulfuric acid to about 0.1 Gm of basic phenylmercuric nitrate, the mixture becomes yellow and the odor of nitro benzene is evolved. Add 1 cc of diluted hydrochloric acid to 5 cc of saturated aqueous solution of basic phenylmercuric nitrate, a white precipitate forms, filter, wash the precipitate with cold water, dry it on a porous plate; the melting point of the product is between 248 and 255 C. Solutions of basic phenylmercuric nitrate respond to the U. S. P. test for nitrate. Add 5 cc of ammonium sulfide solution to 5 cc of a saturated solution of basic phenylmercuric nitrate there is no reaction in the cold; heat the mixture for ten minutes in a boiling water bath; a black precipitate forms.

Add 5 cc of sodium hydroxide solution to 5 cc of a saturated solution of basic phenylmercuric nitrate, no yellow precipitate forms (absence of mercuric ions), the solution does not blacken (absence of mercurous ions). Dissolve 0.1 Gm of basic phenylmercuric nitrate in 150 cc of water, the solution is colorless and clear.

Igute (HOOD) 0.5 Gm of basic phenylmercuric nitrate: the residue does not exceed 0.1 per cent.

Determine the mercury content of an accurately weighed portion of basic phenylmercuric nitrate by a suitable standard method; the mercury content is not less than 62.75 per cent nor more than 63.50 per cent.

Determine the nitrogen content of an accurately weighed portion of basic phenylmercuric nitrate by the micro Dumas method or by the method described in the fifth edition of Methods of Analysis of the Association of Official Agricultural Chemists, page 27, section 27; the nitrogen content is not less than 2.05 per cent nor more than 2.25 per cent.

Determine the phenylmercuric ion content of 0.2 Gm of basic phenylmercuric nitrate dissolved in 90 cc of water and acidified with 10 cc of concentrated nitric acid. Titrate the solution with twentieth normal ammonium thiocyanate, using 2 cc of saturated ferric ammonium sulfate solution as the indicator. Compare the color produced against a blank control containing 0.1 cc of the ammonium thiocyanate solution. Each cubic centimeter of twentieth normal ammonium thiocyanate is equivalent to 0.01389 Gm of phenylmercuric ion; the phenylmercuric ion content found is not less than 87.0 nor more than 87.9 per cent.

MERPHEYL PICRATE TINCTURE 1:200 WITH PICRIC ACID.—Tincture of Phenylmercuric Picrate 1:200 with Picric Acid 12%.—A tincture consisting of acetone 10 per cent, alcohol 50 per cent and water 38.3 per cent, containing phenylmercuric picrate 0.5 per cent with picric acid (trinitrophenol) 1.2 per cent. Phenylmercuric picrate can be considered to have the formula $C_6H_5HgOC_6H_2(NO_2)_3$, although a product of this composition may be difficult to isolate. Solutions which can be considered to contain phenylmercuric picrate may be prepared by the addition of picric acid (trinitrophenol) in appropriate amounts to solutions of phenylmercuric hydroxide.

Actions and Uses.—Merphenyl picrate, in an acetone-alcohol tincture with picric acid, is primarily intended as a prophylactic disinfectant in the preoperative preparation of the intact skin and for recent abrasions, lacerations and wounds. It may also be employed in the treatment of superficial infections, particularly when the drying effect of acetone and alcohol is desired. Owing to its staining quality, the picrate compound is useful to delineate the field or area of application. Picric acid is added in sufficient concentration to provide fair stability, but the amount present is also sufficient to exert some disinfectant action in itself. Because of its high toxicity internally, the possibility of poisoning due to absorption of picric acid from applications of the tincture to large denuded areas of the skin or to mucous membranes should be kept in mind.

Dosage.—For prophylactic preoperative skin preparation, disinfection of soft tissue injuries and the treatment of superficial infections, tincture of phenylmercuric picrate 1:200 with picric acid 12 per cent is applied full strength; in wet dressings or continuous irrigation for infected wounds, a concentration of phenylmercuric picrate not greater than 1:15,000 should be used (prepared by diluting the 1:200 tincture approximately seventy-five times with water). When used as a wet dressing, undue concentration of the diluted solution from unavoidable evaporation should be prevented by the addition of about 0.5 per cent of sodium chloride. Approximately $\frac{1}{2}$ teaspoon of noniodized table salt to each pint of diluted tincture is recommended. This amount of sodium chloride does not produce excessive precipitation. The full strength (1:200) tincture should never be used to wet dressings or bandages.

Manufactured by The Hamilton Laboratories, Inc., Hamilton, Ohio U. S. patent 2,014,676 (Sept. 17, 1935, expires 1952) U. S. trade mark 318,039

Merphenyl picrate tincture 1:200 with picric acid is a strongly yellow colored solution which possesses the odor of acetone and alcohol and a *pH* value of about 2.0 Its specific gravity is between 0.8980 and 0.901 at 25 C.

To 2 cc of merphenyl picrate tincture 1:200 add 2 cc of water and 2 drops of 1 per cent sodium chloride solution a white precipitate, which is soluble in sodium hydroxide and may be reprecipitated by the addition of nitric acid, is formed To 10 cc of merphenyl picrate tincture 1:200 add 2 cc of saturated sodium chloride solution a precipitate forms; filter, wash the precipitate with cold water, dry on a porous plate the melting point of the product is between 248 and 255 C.

To 5 cc of merphenyl picrate tincture 1:200 add 5 cc. of water and 2 cc of diluted nitric acid; extract the solution with three 10 cc. portions of ether; combine the ether extracts, filter through a cotton pledget and evaporate the ether: yellow crystals are obtained which melt at from 120 to 123 C

To 2 cc of merphenyl picrate tincture 1:200 add 2 cc of water followed by 2 cc of potassium iodide solution added a drop at a time; a white precipitate forms in the yellow solution that at no time shows traces of orange or red color and is insoluble in the excess of potassium iodide (*mercuric ions*) To 2 cc of merphenyl picrate tincture 1:200 add an excess of sodium hydroxide solution the solution becomes orange red, but there is no precipitate and the solution does not blacken (*mercurous salts*) To 3 cc of merphenyl picrate tincture 1:200 add 5 cc of sulfuric acid, cool, overlay with a saturated solution of ferrous sulfate, a brown ring does not appear (*nitrate*).

The mercury content of merphenyl picrate tincture 1:200 can be determined by a suitable electrolytic method the mercury content is equivalent to not less than 0.26 per cent nor more than 0.28 per cent of merphenyl ion The merphenyl ion content also may be determined, as directed under merphenyl borate tincture 1:500, after removal by ether extraction of the picric acid from an acidified portion of the tincture (nitric acid)

Caution Merphenyl picrate tincture 1:200 with picric acid is more liable to decomposition on aging than certain other phenylmercuric salts.

MERPHENYL BORATE TINCTURE 1:500.—Tincture of Phenylmercuric Borate 1:500.—A tincture consisting of acetone 4.6 per cent, alcohol 43.2 per cent and water 50 per cent, containing phenylmercuric borate 0.2 per cent, with 1.0 per cent each of boric acid and sodium acid phosphate. Phenylmercuric borate can be considered to have the formula $C_6H_5HgBO_2 \cdot H_2O$, although a product of this composition may be difficult to isolate. Solutions which can be considered to contain phenylmercuric borate may be prepared by the addition of boric acid in appropriate amounts to solutions of phenylmercuric hydroxide.

Actions and Uses.—Merphenyl borate is recognized for use in tincture form for external use as an antiseptic for the prophylactic and therapeutic disinfection of the skin, superficial injuries and wounds. Buffered solutions of this compound are claimed to be somewhat less irritating than certain other phenylmercuric compounds

Dosage.—For prophylactic preoperative preparation of the intact skin, disinfection of recent soft tissue injuries and the treatment of superficial wounds a 1:500 tincture of phenylmercuric borate may be applied full strength; for application to mucous membranes, in wet dressings or continuous irrigation for infected wounds a 1:24,000 concentration should be used (prepared by diluting the 1:500 tincture approximately forty-five times with water). In wet dressings, undue concentration of the diluted solution from unavoidable evaporation should be prevented by the addition of about 0.5 per cent of sodium chloride. Approximately $\frac{1}{2}$ teaspoon of noniodized table salt to each pint of the diluted tincture is recommended. This amount of sodium chloride does not produce excessive precipitation. Dressings and bandages wet with the full strength (1:500) tincture should never be applied.

Manufactured by The Hamilton Laboratories, Inc., Hamilton, Ohio U. S. patent 2,014,676 (Sept. 17, 1935, expires 1952). U. S. trade mark 318,039.

Merphenyl borate tincture 1:500 is a colorless solution which possesses the odor of acetone and alcohol and a *pH* value of about 5.7. Its specific gravity is between 0.920 and 0.940 at 25 C

To 2 cc of merphenyl borate tincture 1:500 add 2 cc. of water and 2 drops of 1 per cent sodium chloride solution: a white precipitate which is soluble in sodium hydroxide and may be reprecipitated by the addition of nitric acid is formed. To 10 cc of merphenyl borate tincture 1:500 add 2 cc of saturated sodium chloride solution: a precipitate forms, filter, wash the precipitate with cold water, dry on a porous plate: the melting point is between 248 and 255 C. Evaporate 5 cc. of merphenyl borate tincture 1:500 on a water bath, cool, add 2 cc of methyl alcohol, ignite the alcohol. The flame is green. To 2 cc. of merphenyl borate tincture 1:500 add 2 cc of water and 1 cc of silver nitrate solution a yellow precipitate forms, soluble in nitric acid

To 2 cc of merphenyl borate tincture 1:500 add 2 cc of water followed by 2 cc of potassium iodide solution added a drop at a time. a white precipitate forms in the solution that at no time shows traces of orange or red and is insoluble in the excess of potassium iodide (*mercuric ions*) To 2 cc of merphenyl borate tincture 1:500 add 2 cc. of water and 2 cc of sodium hydroxide solution: The solution remains clear and does not blacken (*mercurous ions*). To 3 cc. of merphenyl borate tincture 1:500 add 5 cc of sulfuric acid, cool, overlay with fresh saturated solution of ferrous sulfate a brown ring does not appear (*nitrate*).

Transfer 25 cc of merphenyl borate tincture 1:500, accurately measured, to a suitable flask, add 25 cc of water, 10 cc of ferric ammonium sulfate solution and 5 cc of nitric acid, titrate, using fiftieth normal ammonium thiocyanate delivered from a 10 cc buret until the color of the solution matches that of a control containing 50 cc of water, 10 cc of ferric ammonium sulfate solution, 5 cc. of nitric acid and 0.10 cc of fiftieth normal ammonium thiocyanate. Subtract 0.10 cc from the volume noted in the titration, the volume difference is equivalent to not less than 37.5 mg nor more than 42.5 mg of phenylmercuric ion (CoH_5Hg^+). (Each cubic centimeter of fiftieth normal ammonium thiocyanate is equivalent to 5.554 mg of phenylmercuric ion).

SECONAL SODIUM.—Sodium allyl (methyl propyl carbonyl) barbiturate.—Sodium allyl (1-methyl butyl) barbiturate. $CO.Na.CO.NH.CO.C(CH_2:CH:CH_2) [CH(CH_3).CH_2.CH_2.CH_3]$.

Actions and Uses.—The actions and uses of seconal sodium are essentially those of barbitol but it is described as a short-acting barbiturate. It is more active than barbitol and is used in correspondingly smaller doses

Dosage.—The average adult dose is from 0.1 to 0.2 Gm. ($\frac{1}{2}$ to 3 grains). When oral administration is contraindicated, seconal sodium may be administered rectally. Smaller doses of seconal sodium are sedative, larger doses are hypnotic. For use in obstetrics and as a preanesthetic sedative the following dosage has been suggested. In obstetrics, an initial dose of 3 or $4\frac{1}{2}$ grains (0.3 Gm) followed by $\frac{1}{2}$ to 3 grain doses at appropriate intervals up to a total of no more than 12 grains within a twelve hour period; as a preanesthetic agent, 3 to $4\frac{1}{2}$ grains one-half to one hour before the patient is sent to the operating room

Manufactured by Eli Lilly & Co., Indianapolis U. S. patent 1,954,429 (April 10, 1934 expires 1951). U. S. trademark 328,662

Pulvules Seconal Sodium $\frac{3}{4}$ grain (0.05 Gm.)

Pulvules Seconal Sodium $\frac{1}{2}$ grains (0.1 Gm.)

Suppositories Seconal Sodium 2 grains (0.13 Gm.)

DEXTROSE (See New and Nonofficial Remedies, 1941, p. 179).

Baxter Laboratories, Inc., Glenview, Ill., and Don Baxter, Inc., Glendale, Calif. (American Hospital Supply Corporation, Chicago, eastern distributor).

Sterile 20% Dextrose W/V in Physiological Solution of Sodium Chloride in Vacoliter Container. Each hundred cubic centimeters contains dextrose U. S. P. 20.00 Gm. and sodium chloride, 0.85 Gm

Sterile 25% Dextrose W/V in Physiological Solution of Sodium Chloride in Vacoliter Container. Each hundred cubic centimeters contains dextrose U. S. P. 25.00 Gm and sodium chloride 0.85 Gm

The several accepted dextrose solutions in physiological solution of sodium chloride, marketed in Vacoliter Containers, are also supplied in Half Size Vacoliter and Double Size Containers.

SCHIEFFELIN'S COD LIVER OIL CONCENTRATE TABLETS.—A cod liver oil concentrate in the form of tablets. Each tablet has a vitamin A potency of not less than 3,120 units and a vitamin D potency of not less than 312 units when assayed by the method of the U. S. P.

Actions and Uses.—Schieffelin's cod liver oil concentrate tablets possess properties similar to those of cod liver oil so far as these depend on the fat-soluble vitamin content of the latter.

Dosage.—For adults, two tablets three times daily; for children, one tablet three times daily, after each meal; for infants, one tablet daily, crushed and dissolved in the feeding.

Manufactured by White Laboratories, Inc., Newark, N. J. (Schieffelin & Co., New York, distributor). The concentrate used is made under U. S. patent 1,984,858 (Dec 18, 1934, expires 1951).

THEOPHYLLINE WITH ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1941, p. 583).

The following dosage form has been accepted:

Tablets of Aminophylline, 0.2 Gm (3 grains)

Prepared by The Lakeside Laboratories, Inc., Milwaukee

THE REQUIREMENT FOR CALCIUM

Calcium has manifold functions in the human body, not only as a structural factor in the bones and teeth, but also as a prerequisite to normal neuromuscular action and the clotting of blood. Its unique osmotic importance in the blood has been suggested; it exerts a significant influence on the movement and distribution of other mineral elements in the body. This recognized physiologic prominence of calcium has attracted the attention of investigators for many years. It is not surprising that the distribution and availability, the utilization by the organism and the human requirement are still themes of active interest in metabolism and nutrition.

Although milk with its 0.12 per cent of calcium is considered the best source of calcium, vegetables also contribute this element to the diet. When experimental animals are forced to obtain a considerable proportion of their daily calcium from vegetable sources, the availability of this element is definitely less than when milk is the main source of lime. In a recent report Shields and his co-workers¹ showed that, if the availability of calcium in milk is expressed as 100, carrots, fresh lettuce and string beans have the respective values 85, 80 and 74 in this connection. They conclude that there is something in vegetables which decreases the utilization of the contained calcium over that in liquid or dried milk.

Equally important with the availability of calcium from different foods is the efficiency with which the body can utilize the calcium in an excellent source such as milk. An extensive series of studies² from the University of Illinois has recently provided data bearing on this question in preschool children and also in adult human subjects. In all these experiments the conception of degree of utilization was the relationship between

the net calcium loss to the body on a calcium poor basal ration and the supplementary dietary calcium required to eliminate that net loss. When this method of computation was applied to dried or fluid milk it was found that only about 20 per cent of the calcium in this relatively high calcium food was utilized under the conditions of the study by the children and the adults.

The data on which the foregoing conclusions are based permit the calculation of the calcium requirement of man. Two recent reports³ based on studies of a total of sixteen adults in which milk provided a large part of the calcium show essential agreement in daily calcium requirement, the value being 9.6 mg. per kilogram of body weight from one study and 10.7 mg. from the other. These values are greater than the value which is currently looked on as adequate and which is the basis for estimating the nutritive value of dietary programs with respect to calcium. The considerable reserves of the body suggest that temporary shortage of dietary calcium is not of immediate concern. The newer studies, however, will be of value in long range planning of dietaries and in securing greater insight into the problems of mineral metabolism.

SPARING THE LIVER

Addis and his co-workers¹ found that livers of albino rats lose, after a two day fast, 20 per cent of their original protein content, while the kidney, the heart and all other organs and tissues combined lose 4 per cent. The liver presumably is a depot for stored proteins, which may be used during fasting as glycogen is used during fasting. Goldschmidt, Vars and Ravdin² demonstrated in rats that the incidence and the severity of damage to the hepatic cells twenty-four hours after one hour of chloroform anesthesia increases progressively with an increase in the concentration of lipids in the liver. A high protein diet previous to the anesthesia with chloroform reduced the incidence of hepatic cellular necrosis even in livers with a high lipid content and therefore in the face of a severe attack by chloroform. A high concentration of hepatic glycogen, per se, failed to confer protection against the hepatotoxic action of chloroform with the same concentration of hepatic fatty acids and similar intake of proteins. Protection against hepatic injury following a diet high in carbohydrates is apparently due to the reduction of the lipid content of the liver. Miller and Whipple³ demon-

strated in dogs that liver injury due to chloroform anesthesia increases in extent as the protein body stores are depleted. Fifteen to twenty minutes of chloroform anesthesia in a protein depleted dog was frequently fatal with extensive liver necrosis and the typical picture of chloroform poisoning, whereas dogs without protein depletion tolerated ninety minutes of chloroform anesthesia with but little liver injury. Messinger and Hawkins⁴ found protein most effective in protecting dogs against injury to the liver from arsphenamine. A carbohydrate diet was beneficial, though to a lesser degree. Fat in the diet has proved deleterious. When fat fed dogs that showed severe intoxication due to arsphenamine were switched to protein or carbohydrate diets they immediately recovered from the intoxicated state, and the icteric index decreased. Johnson, Ravdin, Vars and Zintel⁵ found in dogs that a diet high in protein and carbohydrates and without fat was most effective in reducing the fatty acid concentration of the liver and in increasing the hepatic glycogen in the presence of obstruction of the common duct. The diet gave the same result as the usual high carbohydrate diet in about half the time. These experiments appear sufficiently conclusive to warrant the adoption of a high protein, high carbohydrate, no fat diet in the preoperative preparation of the patient seriously ill with disease of the biliary tract.

Starling emphasized many years ago that the osmotic pressure of the plasma crystalloids is of minor importance in keeping fluids in the blood vessels, for the crystalloids pass freely in either direction through the walls of the blood vessels. As the plasma protein concentration falls from the normal 7.0 to 7.5 Gm. per hundred cubic centimeters, the osmotic pressure exerted by the plasma is reduced and fluid begins to leave the vessels, causing at first a latent and later an evident edema. The common occurrence of edema among the undernourished peoples in the late war is well known. The evidence is clear that the so-called nutritional edema is due to deficient protein intake and consequent hypoproteinemia. The fundamental cause of edema is hypoproteinemia, and the mechanism is that suggested by Epstein; namely, a reduction in the osmotic pressure of the serum protein.

Jones and Eaton⁶ were first to present evidence that nutritional edema is not uncommonly associated with surgical procedures, particularly of the gastrointestinal tract. The prolonged interference with a normal diet occurring with operations for gastric and duodenal ulcer and gastric cancer results frequently in varying degrees of undernutrition. Hypoproteinemia intensifies

edema of trauma naturally occurring at the site of gastrointestinal suture. Under normal conditions of fluid exchange the edema of trauma begins to disappear forty-eight to seventy-two hours after operation, but in the presence of hypoproteinemia it continues to increase during this period, resulting in a mechanical impediment to the forward progress of gastric contents. Ravdin stresses that attempts to restore a normal fluid and electrolyte balance in the presence of hypoproteinemia, without at the same time increasing the colloid osmotic pressure by adding to the plasma, too frequently results only in adding to the extravascular fluid reservoirs. A diet in which 75 to 80 per cent of the total calories come from carbohydrates and 20 to 25 per cent from protein will prove to be the most satisfactory diet. From 2,500 to 3,000 calories should be given for several days prior to operation and resumed as soon as possible after. The most rapid means of correcting protein deficiency is by repeated plasma transfusions. When more time is available, the orojejunal method described by Stengel and Ravdin⁷ is useful.

INTERFERENCE WITH RADIO COMMUNICATIONS

Electromedical equipment may interfere with radio communication. Physicians do not, of course, desire to interfere with radio communications, but owing to the characteristics of the equipment a portion of the energy may escape the apparatus and appear in space as an unwanted radio signal, thus interfering with communications. Although great progress has been made in the construction of x-ray apparatus, the old type of x-ray equipment is still a source of interference. Efforts have been made to solve this problem in the field of diathermy. Cooperation now prevails among the several interested groups, including the Federal Communications Commission, the manufacturers of electromedical equipment, the radio communications interests and the Council on Physical Therapy, which represents the medical profession.

In countries now at war, drastic steps in the control of diathermy machines have had to be taken. The rule here quoted, placed in effect in 1939, applies in England:

The Postmaster General in the exercise of the powers conferred on him by Regulation 55 of the Defense Regulations, 1939, hereby orders that on and after the 25th day of November, 1939, no person shall, except under the authority of a permit granted by the Postmaster General for the purpose, sell, purchase, let, hire, supply, dispose of, acquire or distribute any of the under-mentioned articles:

(c) High frequency equipment (being equipment which generates or uses high frequency current at frequencies greater than 10,000 cycles per second and having a maximum output exceeding 10 watts), including such equipment intended for use in connection with furnaces and medical apparatus.

In Canada the Radio Division of the Department of Transport has issued a pronouncement in the *Canada Gazette* entitled "Suppression of Inductive Interference from Spark Gap Electro-Medical Apparatus," the first paragraph of which reads:

The necessity of protecting radio communications, including those used by the fighting services, as well as broadcast reception, has obliged the Department of Transport to bring in regulations prohibiting, after January 1st, 1942, the use of spark-gap type diathermy apparatus and mechanical rectifiers for x-ray installations, unless such equipment is adequately shielded, thereby confining the radiation within reasonable limits, or their interference otherwise suppressed.

As far as is known, such steps have not been contemplated here in the United States, even in the event of active war. A technical solution is well known and requires merely the application of certain simple techniques employed in all of the various radio services; for example, screening of the equipment or restricting the high frequency electrical energy to definite frequencies. Undoubtedly an increase in cost of equipment will be entailed, which will be the cost of screening or the additional accessories in the apparatus to regulate the frequency.

The Federal Communications Commission is trying to solve this problem not only without having recourse to licensing, as in England, but without creating any condition likely to place a burden on a practicing physician or increase the cost of diathermy treatments to the public. Since the radio channels affected by diathermy operation are invaluable to the armed forces for other national defense uses, and for many important communications services needed to fulfil the requirements of the general public, the medical profession will of course assist in all ways possible to solve this problem.

Current Comment

AMERICAN MEDICAL ASSOCIATION BROADCASTS

Doctors at Work, the dramatized radio program broadcast by the American Medical Association and the National Broadcasting Company, will go on the air for its second season beginning December 6 from 5:30 to 6 p. m. eastern standard time (4:30 to 5 p. m. central standard time, 3:30 to 4 p. m. mountain standard time, 2:30 to 3:30 p. m. Pacific standard time). The program will be broadcast on upward of seventy-five stations affiliated with the Red Network of the National Broadcasting Company and will be heard from coast to coast. Doctors at Work, a successful serialized story broadcast last year, dealt with the experiences of a fictitious but typical American boy choosing medicine for his vocation and proceeding to acquire the necessary education and hospital training for the private practice of medicine. Interwoven with the personal story of young Dr. Tom Riggs and his fiancée, Alice Adams, was the romance of modern medicine and how it benefits the doctor's patients. The new series of broadcasts will

resume where last year's story left off, namely with the marriage of Tom Riggs and Alice Adams, and depict the subsequent life of a young doctor and his wife in time of national emergency in a typical medium sized American city. The program will be produced under the supervision of the Bureau of Health Education of the American Medical Association. Scripts will be by William J. Murphy of the National Broadcasting Company, author of such successful radio productions as *Flying Time*, *Cameos of New Orleans*, *Your Health*, *Medicine in the News* and last year's *Doctors at Work*. The scripts will again be produced by J. Clinton Stanley, and the National Broadcasting Company orchestra will be under the direction of Joseph Gallicchio as heretofore. Actors will be drawn from the well known group of Chicago radio actors previously heard in American Medical Association and other successful broadcasts. The program will be available at all stations affiliated with the Red Network of the National Broadcasting Company. Announcements should be sought in local newspaper radio columns under the title *Doctors at Work* or possibly American Medical Association or, in some instances, *Health Broadcasts*. Evidence of local interest in the program may be the determining factor in whether a local station takes this educational sustaining feature or sells its time to a local revenue producing program.

ANNUAL CONFERENCE OF SECRETARIES OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

On November 14 and 15 the Annual Conference of Secretaries of Constituent State Medical Associations was held in the headquarters office of the American Medical Association. The keynotes of the current conference were military medical preparedness and extension of plans for the provision of medical service. The program included the following contributions:

The United States Army and Medical Preparedness. L. B. McAfee, Assistant Surgeon General of the United States Army.

The Federal Security Agency and Medical Preparedness. Watson Miller, Assistant Administrator of the Federal Security Agency.

Social Security Medical Problems in Illinois. Charles H. Phifer, President of the Illinois State Medical Society.

Principles Involved in Medical Service and Group Hospitalization Plans. Stanley B. Weld, Editor in Chief of the *Connecticut State Medical Journal*; Peter Irving, Secretary of the Medical Society of the State of New York.

Industrial Health: Progress and Prospects. C. M. Peterson, Secretary of the Council on Industrial Health of the American Medical Association.

How Can the State Medical Journals Best Serve Organized Medicine? Wingate M. Johnson, Editor of the *North Carolina Medical Journal*.

The Responsibilities of the Editorial Staff of a State Medical Journal. Robert N. Nye, Editor of the *New England Journal of Medicine*.

Address. Irvin Abell, Chairman of the Committee on Medical Preparedness of the American Medical Association and Chairman of the Health and Medical Committee of the Federal Security Agency.

The Role of the Medical Profession in the Selective Service System. Lewis B. Hershey, Director of the Selective Service System.

Medical Aspects of Civilian Defense. George Baehr, Chief Medical Officer of the Office of Civilian Defense.

So important were the addresses delivered on this occasion that it is proposed to publish some of them in full in future issues of *THE JOURNAL* and to publish as well a condensed report of such manuscripts and discussions as are not published in the complete report. The statement by Brigadier General Hershey on the present status and forthcoming plans of Selective Service, particularly with relation to the medical aspects of this work, was so important that his paper will be published in full in *THE JOURNAL* for November 29 under the heading of Medical Preparedness.

PROBLEMS CONFRONTING MEDICAL INVESTIGATORS

In a recent address at the fiftieth anniversary celebration of Stanford University, Dr. Walter B. Cannon¹ presented some questions which deserve careful study. The shift in age grouping of the population, with increasing percentages of the elderly and the aged, now widely recognized as a fact, has presented the medical profession with a series of new problems. As one grows older, Cannon points out, the fires of life burn less vigorously and the adjustments of bodily organs to emergencies tend to be impaired—the breath is shorter, the heart beats less effectively, blood pressure gradually rises as the years pass and becomes ill adapted to critical requirements. Are these features essential attributes of the elderly or are they the consequences of comfortable and habitual indolence? In middle age some of these effects may result from inactivity alone and can be reversed by training; is this true in the later decades? If so, should attempts be made to alter them? What, Cannon says, would be the effects if they were altered? These questions offer possibilities for useful research. Almost none of the most prominent disorders of senescence are thoroughly understood. The prevailing ignorance, it may be assumed, is largely due to lack of systematic study. The challenge presented by realization of this fact will doubtless receive many answers. Severe demands on the nervous system, which may have arisen in part from the remarkable shift in the occupation of the citizens, often result in calls for medical attention. A disorder of the brain may fail to be revealed at necropsy or under the microscope. And yet emotional upsets which leave in the nervous pathways no visible trace have concrete and obvious effects and may be the occasion for profound misery and suffering. The gradual onset of disabilities, bodily and mental, in the later years of life demands, Cannon believes, long range studies on the possible influence of inheritance, early injuries, severe infections in childhood and youth, frustrated plans, the demands of labor and probably many other conditioning experiences. Cannon also calls attention to the disastrous cooperation of disease, pain and early death when warring hosts or nations battle against nations for supremacy. International developments unquestionably have affected medical research in a warping of scientific activities away from untrammelled

pursuits toward problems of military significance. Medical investigators, however, by learning the nature and cure of malnutrition, by devising appropriate treatment for shock and hemorrhage and in many other ways have served to mitigate the torments and ravages of warfare. One of the results of the present war already has been a more intimate association of a highly desirable nature with medical investigators in Latin American nations. Finally Cannon emphasizes as one of the biggest problems facing medical investigators the filling of their own ranks. This is indeed primary, and, unless well equipped recruits can be attracted to the career of the investigator, progress will end. Cannon dwells at some length on the attractions and rewards of medical investigators, pointing out particularly one consideration eminently creditable to their efforts: "Because life and health are precious and medical research is deeply concerned with protecting life and health, the triumphs of that research are put to use without regard to any national or racial difference. . . . Even though the beneficiaries may despise their benefactors, they must receive the benefactions. . . . The conquest of a disease, it should be remembered, is a permanent conquest."

NEW AND NONOFFICIAL REMEDIES DESIGNATED IN NEW HAMPSHIRE LAW

An act relating to the sale of drugs in New Hampshire was approved on June 13 and took effect on October 1. This law, which is intended to curb further the promiscuous or unlicensed sale of potent drugs, designates, as standard compendiums for use in determining the drugs affected, the United States Pharmacopeia, the National Formulary and New and Nonofficial Remedies. The latter volume lists and describes the articles that stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1 of the year of publication. The descriptions of accepted articles are based in part on investigations made by, or under, the direction of the Council and in part on evidence or information supplied by the manufacturer or his agents. Statements made by those commercially interested are examined critically and admitted only when they are supported by other evidence or when they conform to known facts. New and Nonofficial Remedies, which is only one of the books published under the authorization of the Council on Pharmacy and Chemistry, is intended chiefly for the physician, but it has proved of value to others who are concerned with medicinal preparations including manufacturers of pharmaceutical products, pharmacologists, governmental institutions, teachers and students. Designation of this volume in the New Hampshire Law is one more well deserved recognition of the Council's thirty-six years of continuous efforts to expose deceptions practiced on the medical profession and to evaluate proprietary drugs detailed to the profession. These efforts have contributed greatly to rational therapeutics.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

EQUIPMENT AND OPERATION OF EMERGENCY MEDICAL FIELD UNITS

MEDICAL DIVISION—BULLETIN NO. 2

Prepared by Office of Civilian Defense, Washington, D. C.
(See THE JOURNAL, Aug. 30, 1941, p. 793)

This bulletin supplements Medical Division Bulletin No. 1, which deals with the organization of Emergency Medical Service for Civilian Defense. The Office of Civilian Defense recommends that state and local defense councils adopt the plans set forth in these bulletins so as to secure the advantages of uniformity in organization, equipment and operation of Emergency Medical Field Units. In the event of a civilian disaster, adjacent communities which have adopted this common pattern can pool or exchange their resources. The adoption of uniform equipment standards during the national emergency is desirable also because of priorities in materials and manufacture. The recommended equipment conforms as far as possible, therefore, with that of the Medical Department of the U. S. Army.

The Field Casualty Service

As recommended in Bulletin No. 1 of the Medical Division, emergency medical field units should be established in all approved general hospitals, both voluntary and governmental, located in coastal states and in industrial centers of the interior. The plan of organization and size of the emergency field units for hospitals of various sizes and the total number of field units recommended on a population basis are outlined in Bulletin No. 1.

The emergency medical field units of a hospital are composed of two or more squads, so that at least one squad is on first call during each twelve hour period of the day. In larger hospitals reserve squads should be available at the call of the control center in the event that multiple sites of disaster should require the manning of additional casualty stations and first aid posts. All members of emergency medical field units should be systematically drilled in first aid procedures.

To be prepared to respond promptly and effectively, emergency medical units should also participate in field drills. These drills should be called by the local defense authority and should include police and fire auxiliaries, rescue squads, stretcher teams, transport and canteen services so that the local protection services may be integrated.

It is the considered opinion of the Medical Advisory Board of the Office of Civilian Defense that the medical field units should be related to hospitals. During the present period of preparation, prompt availability in the event of sudden and unexpected disaster can be expected only of units organized largely from the intern and resident staffs. It is advisable to designate an assistant surgical resident or surgical intern as squad leader. In order not to deplete the surgical staff of the hospital other members of emergency squads may be derived from the medical, pediatric and other nonsurgical divisions of the hospital.

Reserve Squads.—In the event of the more remote possibility of prolonged and continuous need for service in casualty stations and first aid posts, it would become necessary to replace most of the hospital personnel assigned to the field casualty service. Reserve squads made up of medical, nursing and trained volunteer personnel from the community would carry the major responsibilities for the field service. Until the need is demonstrated, it will be simpler and more efficient to concentrate the primary organization of emergency medical field units for the most part within approved hospitals.

In hospitals whose resident staff should not be depleted even for a temporary emergency, the primary medical field unit may

be organized in part or even wholly from physicians and nurses engaged in private practice in the community.

Operation of Field Casualty Service.—The operation of the field casualty service may be sketched as follows: Air raid warnings will come to the local control center from the military establishment in the area and will be relayed to the proper civilian defense officers. Information concerning the location and extent of local damage will be transmitted promptly to the control center by air raid wardens and other observers. Using a spot map showing the location of hospitals and sites for casualty stations, the control center or its substation will call out an appropriate number of emergency medical field units.

The squads of the emergency medical units which have responded will proceed to the sites to which they have been directed by the control center or its substation and set up casualty stations. When indicated, the squad leader in charge of a casualty station may dispatch one or more teams of physician, nurse and nursing auxiliaries to establish first aid posts at sites closer to the disaster. The establishment of fixed first aid posts and casualty stations is not at present contemplated.

CASUALTY STATIONS

The casualty station will occupy a predetermined site such as the clinic of a hospital, health department or voluntary agency, a health center or substation, a school basement or other suitable place which provides shelter, protection and accessibility. It should be located if possible on a side street so that ambulances will not block main thoroughfares. The sites selected for casualty stations should be numbered and indicated on a spot map of the community. The casualty station will:

1. Serve as a center from which medical teams may be sent closer to the disaster if required.

2. Care for the less severely injured and for persons suffering from shock and hysteria until they may be permitted to return to their homes or to temporary shelters. This will protect hospitals from the burden of minor casualties which would interfere with the work of caring for the seriously injured.

3. Keep a record of all persons treated at the station and see that all casualties transferred to a hospital are tagged.

The casualty station is to be supplied with stretchers, collapsible cots and blankets from medical depots located at sites from which the transportation of emergency medical service is derived. Eight stretchers, twenty-four cots and sixty-four blankets should be available per 10,000 of population for issue to casualty stations as the need arises. Where kitchen tables are not available at the location of a casualty station, two pairs of saw horses, each 36 inches high, may be required, on which stretchers may be placed to serve as dressing tables. Stretcher teams and rescue squads will obtain their stretchers at casualty stations.

FIRST AID POSTS

The first aid post will occupy a temporary location usually close to the scene of disaster and will:

1. Care for the more severely injured, preparatory to their transfer to a hospital. No surgery other than emergency first aid is contemplated.

2. Classify the casualties so as to expedite the transfer of the seriously injured to a hospital—a most important responsibility which requires surgical judgment.

3. Direct the stream of ambulatory and of slightly injured stretcher patients and those suffering from shock or hysteria to a casualty station.

4. Tag all casualties immediately. Maintain entries in the casualty record book of all persons receiving first aid. (A nurse or nurse's aide is to be responsible for these records.)

LIST 1.—Equipment for a First Aid Post
(Working supply for one physician's team)

Equipment for Emergency Medical Field Units

The following lists include only the minimum medical and surgical equipment required for emergency treatment at the site of a disaster. Provision for other than essential minor surgery has purposely been omitted.

The equipment for each physician and his team is to be carried in two portable boxes provided with handles. These two boxes should be of the same size (15 by 20 by 8 inches) and may be packed conveniently in the ambulance or other vehicle transporting the emergency squad to the site of the casualty station. The provision in separate containers of working supplies for

each physician will permit the squad of a casualty station to split off one or more teams of physicians and assistants who can be dispatched with their equipment to set up advanced first aid posts.

EQUIPMENT FOR A FIRST AID POST

List 1 indicates the medical and surgical equipment for each physician of an emergency medical field unit and his team of nurse and orderly or nurses' aide. One or more such teams man a first aid post. First aid posts are subsidiary to a casualty station which will furnish replacements of drugs and surgical supplies.

EQUIPMENT FOR A CASUALTY STATION

List 2 indicates the equipment for a casualty station. It contains bulky articles, such as traction splints, which could not be included in the equipment of the first aid post without impairing its mobility. These articles will be issued from the casualty station to the first aid posts as the need arises. Casualty stations are also stocked with dressings, bandages and drugs from which the supplies of the first aid posts may be replenished. Blood, plasma and biologic products such as tetanus antitoxin or toxoid may be obtained by casualty stations from the parent hospital as needed. They are, therefore, omitted from this list.

LIST 2.—Equipment for a Casualty Station
(Emergency squad of two or four physicians, nurses
and nursing auxiliaries)

Identification Tags

The identification tag (fig. 1) is to be filled out by the first member of a rescue squad, stretcher team or first aid post to reach the casualty. This must be done immediately, because

the patient may lose consciousness. All the required information should be recorded. Information concerning the name and address of the injured and of the "person to be notified" are important to those anxious to locate the injured person. The place where an unconscious patient was found should be noted, as this may be the only clue to his identity.

It is important to record administration of narcotics or application of a tourniquet. Further treatment given at the first aid post or casualty station should be indicated on the back of the identification tag. Warnings concerning possible internal injury, hemorrhage or skull fracture should also be noted on the back of the tag to facilitate sorting of patients on arrival at the hospital.

The tag should be affixed securely to the patient and not to clothing which might later be removed.

IDENTIFICATION TAG	
Name	(Surname) (Given name)
Address	
Age	
Male <input type="checkbox"/>	Catholic <input type="checkbox"/> Single <input type="checkbox"/> White <input type="checkbox"/>
Female <input type="checkbox"/>	Protestant <input type="checkbox"/> Married <input type="checkbox"/> Negro <input type="checkbox"/>
	Jewish <input type="checkbox"/> Widowed <input type="checkbox"/> Other <input type="checkbox"/>
Person to be notified:	
Name	
Address	
Phone	Relation
Where tagged	
Date	194... Hour ... M.
Diagnosis:	
Treatment given:	
Morphine	Tourniquet
Where sent	
Signed	
Organization 16-23451 GPO	

Fig. 1.—Identification tag. This measures $3\frac{3}{4}$ by 6 inches, and the back is used for supplementary information.

A set of symbols to indicate the necessity for priority treatment has been devised to facilitate sorting of patients at the hospital. These symbols should be drawn prominently on the forehead of the patient at the first aid post or casualty station with a red skin pencil:

- U Urgent—requiring priority attention.
- TK Tourniquet.
- T Indicating tetanus antitoxin has been given.
- H Internal hemorrhage.
- M $\frac{1}{4}$ Indicating $\frac{1}{4}$ grain of morphine or
- M $\frac{1}{2}$ $\frac{1}{2}$ grain given.

In addition, a casualty record book will be part of the equipment of each physician's team (fig. 2). A nurse or nurses' aide should be assigned the responsibility for entering a record of every patient seen. This record should include the diagnosis, treatment and disposition.

Emergency Medical Service

It is important that each local defense council in the states along both seaboard and in industrial centers in the interior appoint without delay a chief of Emergency Medical Service

who shall be responsible to the local director of civilian defense for the organization of the Emergency Medical Service described in Medical Division Bulletin No. 1. He should be an outstanding medical leader and it is advisable that he be selected in consultation with the state defense council, the local medical society and the local health officer. To facilitate the integration of all local medical resources into a comprehensive program for civilian protection, it is recommended that the local chief of Emergency Medical Service be assisted by a medical advisory council consisting of the local health officer, an experienced hospital executive and representatives of the local medical society, the nursing profession, the American Red Cross and participating voluntary agencies.

DUTIES OF THE LOCAL CHIEF OF EMERGENCY MEDICAL SERVICE

Under the administrative authority of the local director of civilian defense, the duties of the local chief of emergency medical service are:

1. To determine the scope of the activities of all official and voluntary organizations which are to participate in the emergency medical program of civilian defense, to integrate these organizations into the comprehensive local program and to assist them in expanding their activities to the limit of their resources in personnel and equipment.
2. To assist hospitals in the locality to organize, equip and train emergency medical field units as outlined in Medical Division Bulletin No. 1, "Emergency Medical Service for Civilian Defense."
3. To inspect and select sites for the establishment of casualty stations.
4. To make a spot map of the locality, indicating the locations of hospitals, appropriate sites for casualty stations, depots for storage of stretchers, blankets and collapsible cots and the locations of rescue squads. The map should indicate the number of emergency medical squads in each hospital. Copies of the map should be supplied to control centers, police and fire departments, the health department, the local Red Cross chapter, the state defense council, the regional director, the regional medical officer and to all cooperating hospitals.
5. To plan and establish adequate transportation service for casualties and medical personnel in consultation with local government departments, the American Red Cross and voluntary agencies.¹
6. To arrange with the local control authority for field drills of emergency medical units and rescue squads in collaboration with police and fire auxiliaries, disaster relief and canteen services of the American Red Cross, the ambulance transport service and other civilian defense units and to supervise such drills.
7. To make an inventory of hospital beds in the locality and of the possibilities for emergency expansion in bed capacity.
8. To assist the authorities charged with preparing plans for evacuation in making an inventory of hospitals, convalescent homes, sanatoriums, hotels and other structures within a radius of 50 to 100 miles which might be used as base hospitals to which patients in city institutions could be evacuated.
9. To assist the local volunteer office in establishing courses for volunteers in the field of health, medical care, nursing and related activities.
10. To stimulate recruitment of volunteers for nurses' aide courses of the American Red Cross, assist the local Red Cross chapter in establishing training centers for volunteer nurses' aides at appropriate hospitals and assist the Red Cross placement bureau in placing nurses' aides with hospitals, clinics, health departments and field nursing services after completion of training.
11. To stimulate and guide extension of first aid training courses as widely as possible among the local population through the American Red Cross and other official and voluntary agencies.
12. To stimulate and guide industrial plants, business establishments and government bureaus in the locality in the training

1. A bulletin on transportation for the Emergency Medical Service is in preparation. It will include plans for stretcher teams, messenger service, ambulance and other transport needs of the Emergency Medical Service.

15. To keep the community and particularly the members of the health and medical professions and the participating official and voluntary organizations informed of the plans and activities of the local emergency medical service

Decontamination squad—A group of auxiliaries of the sanitation department trained and equipped to decontaminate localities and structures in order to rid them of persistent chemical agents

Ninth Civilian Defense Region—233 Sansome Street, San Francisco

BLOOD PLASMA NEEDED FOR THE ARMY AND NAVY

The Surgeon General of the Army, Major Gen. James C. Magee, has advised the American Red Cross that 1 pint of blood from each of one hundred thousand volunteer donors is required to meet the current emergency needs in the U. S. Army in this country and elsewhere. This need, General Magee said, is immediate and is not a project to collect and store blood for future use in case of war. If the country became involved in war, a far greater amount of blood plasma would be needed. It was also revealed that the U. S. Navy needs 100,000 units of blood plasma.

The Red Cross, therefore, is putting into effect plans for a great expansion in blood donor facilities. Whereas now blood donations are being made in seven cities, the Red Cross in the immediate future will have twenty-two local chapters engaged in this activity. Whereas only one laboratory is now engaged in processing the blood donated, the national director of the blood donor service, Dr. G. Canby Robinson, said that arrangements have been made with seven laboratories for the processing of the blood donated. These laboratories are doing this work on a nonprofit basis, and the Army and Navy pay only for the actual processing, as the blood is collected and shipped to the laboratories by the Red Cross. Some of this dried blood plasma has already been shipped for use in the present maneuvers in North and South Carolina, and other units have been shipped to our foreign outposts and to the Navy. Recently in the torpedoing of the U. S. S. *Kearny* the important role of blood plasma was illustrated in the saving of the life of a sailor who now is recuperating in a hospital in Iceland. In this case the blood plasma was dropped by parachute from a plane into the sea, then recovered from the sea and resterilized and administered to the sailor aboard the torpedoed vessel. The sailor, whose life had been considered in grave danger, showed steady improvement after several transfusions with the blood plasma.

THE NURSING REPRESENTATIVE IN THE LOCAL MEDICAL ADVISORY COUNCIL

Medical Division Bulletin No. 1, "Emergency Medical Service for Civilian Defense," of the Office of Civilian Defense, recommends the appointment of a nurse on the local medical advisory council in order to promote effective cooperation between the chief of emergency medical services, the local Red Cross chapter, the hospitals and the health and nursing agencies in the area. This council is to assist the chief of emergency medical services in integrating all local health and medical resources into the civilian defense program.

In selecting the nursing member, the Medical Division of the Office of Civilian Defense recommends that the following qualifications be observed:

1. She should be a graduate registered nurse.
2. She should be active in the nursing profession and be recognized by the local nurses as a leader.
3. She should be available to attend meetings.

If the nursing representative on each local medical advisory council is selected on this basis, she will secure the cooperation of the entire nursing profession in the training and subsequent use of volunteer nurses' aides.

CIVILIAN DEFENSE WEEK

During Civilian Defense Week, Friday, November 14, was designated "Health and Welfare Day" in order to emphasize the importance of a healthy population as the foundation for strong military defense, to minimize the economic and social disturbances caused by the impact of the defense program and to promote the cause of physical well-being.

On Health and Welfare Day, emphasis was placed on the fact that protection of civilians includes protection of their physical well-being by proper exercises, nutrition and medical care, protection of their social welfare by adequate economic security and by adequate educational, recreational and housing facilities.

Every state defense council already has a nutrition committee whose function it is to see that local defense councils in every community pay close attention to the matter of proper food.

The Office of Civilian Defense has initiated a national program to promote physical fitness under the general direction of John B. Kelly, assistant director, a famous Olympic athlete. This program, in which national figures in the field of sports have been recruited, is projecting a national program which, it is expected, will affect the physical training of every man, woman and child in the nation.

The Medical Division of the Office of Civilian Defense has initiated a program of Emergency Medical Service designed to affect communities of every size, to meet conditions occasioned by actual attack. These plans include base hospitals, evacuation and clearance hospitals, casualty stations, first aid posts, decontamination stations, transportation services, emergency public health nursing, emergency water and food protection, canteen facilities and every service that would be essential under emergency conditions.

BUNDLES FOR BRITAIN

Bundles for Britain, Inc., 745 Fifth Avenue, New York City, cabled funds totaling \$20,760, about November 1, to the London headquarters to assist twenty nongovernment hospitals in England and the British Red Cross and people of the Orkney and Shetland Islands. The largest gift in this sum was \$3,000 from Charlotte, N. C., for the Royal National Orthopedic Hospital in London. Many other branches of this organization were represented in the funds cabled, some of which earmarked their contributions for certain designated hospitals or for the purchase of some particular type of medical equipment. Some of the branches contributing to this fund were from far away, as Hawaii and Alaska.

PADEREWSKI HOSPITAL NEEDS EQUIPMENT

An appeal has been made by the Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York, for funds to purchase equipment for the Paderewski Hospital in Edinburgh, Scotland. Ten thousand dollars is wanted for the purchase of five operating sets, one portable x-ray unit, five thousand three hundred assorted instruments, nineteen physicians' first aid kits, two hundred gross of x-ray films and various biologic preparations. In response to a previous appeal from this hospital, supplies valued at more than \$7,000 were ready for shipment abroad the week of October 20.

DEFENSE ASPECTS OF PUBLIC HEALTH

Meetings were held at Herman Kiefer Hospital, Detroit, November 5, 12 and 26, for physicians in the Detroit area to study defense aspects of public health. The first meeting was addressed by Dr. Thomas Francis of the University of Michigan on "Influenza Control as a Problem in National Defense." These meetings are sponsored by the Wayne University College of Medicine, the Wayne County Medical Society and the Detroit Department of Health and other professional groups.

NAVY CONSULTANT APPOINTED

The Surgeon General of the Navy announced the appointment of Dr. Wilbur A. Sawyer, the director of the International Health Division of the Rockefeller Foundation, as an honorary consultant to the Medical Department of the U. S. Navy.

NAVY MEDICAL MEETING

At a meeting of the medical and dental officers of the U. S. Navy at the Naval Medical School, Washington, D. C., November 3, Lieut. Comdr. LeRoy D. Fothergill, M. C., discussed "The Problem of Diphtheria in the Armed Services."

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY SECOND CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Second Corps Area, which comprises the states of New York, New Jersey and Delaware:

ALTERBAUM, George, 1st Lieut, Brooklyn, Camp Davis N C
AYARS, Lawrence S, 1st Lieut, Roslyn Heights, N Y, Camp Blinding, Fla
BAKER, Augustus L, Jr, 1st Lieut, Dover, N J Fort Jay, N Y
BEIN, Solomon S, Captain, Brooklyn, Mitchell Field, N Y
COHN, Mortimer M, 1st Lieut, Brooklyn, Camp Folk, La
CRILLY, James A, 1st Lieut, Elizabeth, N J, Fort Jackson, S C
D'AGATI, Vincent C, 1st Lieut, Jackson Heights, N Y, Fort McClellan, Ala
DORMONT, Richard Edward, 1st Lieut, Brooklyn, Fort Bragg N C
DUBINS, Henry B, 1st Lieut, Brooklyn, Fort Jackson, S C
FISHER, Hyman, Major, Laurelton, L I, N Y, Camp Wheeler Ga
GARSON, Byron Jerome, 1st Lieut, New York, Fort McPherson, Ga
HELDMAN, Arthur, 1st Lieut, New York, Camp Shelby, Miss
HERZFELD, Melvin G, Lieut Colonel, New York, Camp Gordon, Augusta Ga
JELSONINO, Samuel J, 1st Lieut, Buffalo, Fort Niagara, N Y

FIFTH CORPS AREA

The following additional medical reserve corps officers have been ordered to duty by the Commanding General, Fifth Corps Area, which comprises the states of Ohio, West Virginia, Indiana and Kentucky:

BIZOT, William H, 1st Lieut, Louisville, Ky, Erie Proving Ground, Lacarne, Ohio
DAVIS, Daniel, 1st Lieut, Toledo, Ohio, Camp Perry, Ohio
DORMANN, Jack, 1st Lieut, Indianapolis, Fort Knox, Ky
EARP, Evason B, Major, Indianapolis, Camp Perry, Ohio
HALL, Joseph E, 1st Lieut, New Cumberland, W Va, Fort Thomas, Ky
HANIFAN, Richard K, 1st Lieut, Clarksburg, W Va, Fort Knox, Ky
HUGHES, Carlisle B, Jr, 1st Lieut, Huntington, W Va, Fort Knox, Ky
JOHNSTON, Donald D, Lieut Col, Fort Wayne, Ind, Fort Hayes, Ohio
JONES, Paul A, 1st Lieut, Lyons, Ind, Fort Hayes, Ohio
KIRCH, Leo N, 1st Lieut, Indianapolis, Fort Benjamin Harrison, Ind
McCANN, Harold F, 1st Lieut, Clarksburg, W Va, Camp Shelby, Miss

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Eighth Corps Area, which comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas:

ATKINS, Paul N, 1st Lieut, Muskogee, Okla, Station Hospital, Fort Sill, Okla
AULT, Charles A, 1st Lieut, Dallas, Texas, Station Hospital, Fort Sam Houston, Texas
BERSHOF, Edward, 1st Lieut, Denver, Station Hospital, Fort Sam Houston, Texas
CARRINGTON, William L, 1st Lieut, Mexico, Texas, Station Hospital, Fort Sam Houston, Texas
CHEATWOOD, William R, 1st Lieut, Ada, Okla, Station Hospital, Camp Wallace, Texas
CLARK, Richard Gwyn, Captain, Gainesville, Texas, Station Hospital, Fort Sill, Okla
COATES, Ruge Reginald, 1st Lieut, Oklahoma City, Station Hospital, Fort Sill, Okla
ELLISON, Grayfree, 1st Lieut, Norman, Okla, Station Hospital, Fort Sill, Okla
LINTER, Marcus H, 1st Lieut, Phoenix, Ariz, Station Hospital, Fort Bliss, Texas
GOTTLICH, Arthur Paul, 1st Lieut, Dallas, Texas, Station Hospital, Fort Sill, Okla

ALLEN, Lloyd R, Lieut Col, Colorado Springs, Colo
ARRINGTON, John H, 1st Lieut, Wichita Falls, Texas
BARRETT, John H, 1st Lieut, Palestine, Texas
CHRISTMAN, Edmund L, 1st Lieut, Joplin, Mo
CLARK, Ralph O, 1st Lieut, Oklahoma City
COLLINS, William A, 1st Lieut, El Paso, Texas
DAY, Meriwether L, 1st Lieut, Phoenix, Ariz
FARNUM, Lorenzo M, Jr, 1st Lieut, Oklahoma City
FRISSELL, Ben P, Captain, Phoenix, Ariz
JOHNSON, Emmett R, 1st Lieut, Topeka, Kan

ADAMS, Blair S, 1st Lieut, Camp Huachuca, Texas
BOERSMA, Donald, 1st Lieut, Fort Bliss, Texas
LLINAS, Marvin, 1st Lieut, Fort Sill, Okla

JONES, John A, 1st Lieut, New York, Fort Dix, N J

ORGANIZATION SECTION

MEDICAL ECONOMIC ABSTRACTS

MEDICAL CARE FOR SOCIAL SECURITY CLIENTS IN ILLINOIS

The Illinois Department of Public Welfare has issued instructions to county medical advisory committees concerning the methods of supplying medical care to persons receiving old age assistance or who fall under the aid to dependent children program. The federal government will match state funds for old age assistance only when monthly payments are made directly to the recipient. Payments for services cannot be made directly to professional practitioners. All old age assistance is limited to \$40 a month. If the total does not amount to \$40, an allowance to meet the cost of medical or dental care may be included in the monthly payment when the need for such care has been established. This is determined through discussion by the recipient with the county department of public welfare. The need for such care must be established through statements by physicians giving diagnosis and cost of medical care.

It is possible to include a small medical allowance without a physician's recommendation for the purpose of meeting the recipient's "medicine chest" needs. If it is not possible to include the cost of medical care within the \$40 monthly maximum, medical and surgical or hospital care may be authorized by the township supervisor. The federal Social Security board has recommended an amendment to the federal Social Security act by which funds may be turned over to the state specifically for medical care purposes without the requirement of cash payment to the recipient. If this amendment becomes a law and is followed by appropriate state enabling legislation, direct payments may be made to physicians and dentists for services given to old age pensioners and dependent children.

The Division of Public Assistance has asked the Illinois State Medical Association to cooperate in planning a medical care program, and the division has been meeting with a state advisory committee on medical care since January 1941. The Illinois State Medical Association was requested to appoint county medical advisory committees. These committees will cooperate with the county departments in medical matters. The Division of Public Assistance states that its "medical care program has been planned so that the traditional relationship between the patient and the physician may be continued and a free choice of physician recognized."

PHYSICIANS GO TO SMALL TOWNS

To test the truth of the allegation that recently graduated physicians refuse to practice in small towns, Dr. J. F. Hassig, secretary of the Kansas State Board of Medical Registration and Examination, made a survey of the sizes of the towns in which physicians have found locations during the past ten years.¹ The result of this study is given in the accompanying table.

According to the census of 1930 there were 411,202 persons living in the towns of 5,000 population or less, and the survey showed that 203 physicians started practice in these towns.

Locations of Physicians by Size of Towns

Year	Under 1,000	1,000 to 2,000	2,000 to 3,000	3,000 to 4,000	4,000 to 5,000	5,000 to 10,000	10,000 to 15,000	15,000 to 20,000	20,000 to 30,000	30,000 to 125,000
1930.....	8	5	6	4	1	3	5	1	4	6
1931.....	4	4	5	1	0	5	8	7	1	11
1932.....	7	7	1	3	2	7	7	1	2	13
1933.....	5	4	0	4	6	1	10	2	2	7
1934.....	8	5	6	2	0	2	8	0	2	17
1935.....	5	4	4	3	4	7	7	3	2	20
1936.....	10	7	1	3	4	7	7	1	2	21
1937.....	4	9	5	3	2	4	9	0	1	21
1938.....	8	8	4	1	3	3	13	2	1	19
1939.....	5	4	1	0	3	1	7	4	3	34
Total..	64	57	33	24	25	40	81	21	20	100

In the cities having more than 5,000 population there were 622,979 persons, and 332 physicians started practice in these during the decade. It is impossible to determine to what extent the approximately 850,000 persons living outside any incorporated place were served by the physicians in the different size cities, but the study would certainly seem to indicate that the smaller cities have not been avoided by physicians entering practice.

Kansas has no county not served by a doctor of medicine, no areas more than 30 or 35 miles from a hospital, and the overwhelming majority of its areas are 10 or 15 miles or less distance from a hospital. It has almost the national average of population per physician, and its age groups of physicians and its specialists are well distributed throughout the state.

1. Locations, editorial, J. Kansas M. Soc. 42: 299 (July) 1941.

WOMAN'S AUXILIARY

Pennsylvania

Dr. Chester K. Kistler, president of the Berks County Medical Society, recently presented awards to the winners of the Health Essay Contest conducted by the auxiliary in the high schools of Berks County. Eleven schools entered the contest and 168 essays were submitted. Six prizes were awarded.

The Philadelphia County auxiliary recently held its eleventh annual Health Institute. The speakers were Dr. Francis F. Borzell, president of the state medical society; Major James B. Mason, unit instructor of the Medical Reserve Corps; Capt. John B. Kaufman, district medical officer, Fourth Naval District, U. S. Navy; Dr. Malcolm W. Miller, allergist at the Lankenau Hospital, Philadelphia; Mrs. Maxwell Lick, president of the state auxiliary; Dr. Leon H. Collins Jr., chairman of the Pneumonia Control Committee of the Philadelphia County Medical Society; Dr. Edward A. Strecker, consultant at the Pennsylvania Hospital, Philadelphia, and Dr. Edward L. Bortz, president of the Philadelphia County Medical Society. A tribute was paid to Mrs. Wilmer Krusen, the founder of the

Health Institute. Mrs. Krusen was elected an honorary member of the auxiliary and presented with a bouquet of flowers. The theme of the institute was "Medicine and the National Crisis" and was prepared by Dr. Bortz.

Texas

The Henderson County auxiliary met, September 16, at the home of the president, Mrs. B. C. Wallace of Athens, who gave a report of the recent meeting of the state executive board at Dallas. Mrs. R. H. Hodge read an article entitled "Our Ailing Mental Hospitals."

The Smith County auxiliary at its last meeting in the spring voted to dispense with the usual auxiliary program, meeting instead on the regular meeting day as a unit with the local Red Cross chapter in the surgical dressings department. Auxiliary dues will be paid and affiliation maintained with the state and national auxiliaries. Business meetings will be held each month as in the past. Each member will serve from 9 a. m. until 12 noon in the rooms of the Red Cross chapter on the regular meeting date, which the Smith County auxiliary has voted as its part in the defense program.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 1817.

CALIFORNIA

Meeting on Nutrition.—Helen S. Mitchell, Ph.D., director of nutrition for the Federal Security Agency, Washington, D. C., was the speaker at a conference of representatives of professional groups of Southern California, November 12, under the auspices of the state nutrition for defense committee and the nutrition committees of the Southern California counties. Dr. Mitchell was formerly research professor of nutrition at Massachusetts State College, Amherst, Mass.

FLORIDA

New County Health Unit.—Okaloosa and Walton counties have set up a full time health service. The two units will be operated independently with separate staffs but will be under the supervision of Dr. Charles W. McDonald, Marianna, who will divide his time between the two counties, newspapers reported.

District Meetings.—The Southeast Medical District Society held its fifth annual session in Hollywood, October 30. Among others, the following spoke: Drs. Eugene C. Chamberlain, Fort Lauderdale, "Digitalis Poisoning"; Lloyd J. Netto, West Palm Beach, "Unrecognized Importance of Minor Injuries," and Gilbert S. Osincup, Orlando, "Observations as a Result of Six Years of Early Feeding of Infants."—Speakers before the fifth annual session of the South Central Medical District Society in Orlando, November 1, included Drs. Thomas M. Rivers, Kissimmee, on "Relation of Vitamin B Complex to Human Pathology"; Don D. C. C. Robertson, Orlando, "Use of Eucupin Solutions in the Production of Prolonged Postoperative Analgesia in Rectal Surgery," and John Randolph Perdue, Miami, "Cesarean Section—A Ten Years Study."—The Southwest Medical District Society was addressed at its fifth annual session in Bartow, October 31, among others, by Drs. David R. Murphey Jr., Tampa, on "Use of the Miller-Abbott Tube in Cases of Intestinal Ileus"; Joseph J. Ruskin, Tampa, "Spinal Anesthesia," and Arthur H. Weiland, Coral Gables, "Rehabilitation of Child Following Anterior Poliomyelitis."

ILLINOIS

Personal.—Dr. Samuel W. McKelvey, Belleville, has been appointed consulting surgeon for state hospitals at Alton and Jacksonville, it is reported.—Dr. Clifford U. Collins was guest of honor at a banquet given by the Peoria Medical Society, October 8, in recognition of his completion of fifty years in the practice of medicine, all spent in Peoria. He was granted membership in the "Fifty Year Club" of the state medical society.—Dr. Victor M. Brian, Lawrenceville, has been elected chairman of the health division of the petroleum section of the National Safety Council, Chicago.—Dr. Herbert L. Pettitt, Morrison, has been named assistant health director of the state department of public health, with headquarters in Springfield.—Dr. William M. Miller, Cabery, has received a gold plaque from the Illinois Central Railroad, denoting his completion of fifty years' service.

Chicago

Personal.—Dr. Lloyd L. Arnold has been given a year's leave of absence as professor of bacteriology and public health, University of Illinois College of Medicine, to finish writing a textbook on preventive medicine and public health, it is reported.—Dr. Leo A. Kaplan has been appointed assistant director of the behavior clinic of the Criminal Court of Cook County.

Society News.—Dr. Horton C. Hinshaw, Rochester, Minn., will address the Chicago Tuberculosis Society at the Bismarck Hotel, November 27, on "Chemotherapy in Experimental Tuberculosis."—Dr. Gladys R. H. Dick addressed the American Medical Women's Association, Branch No. 2, November 12, on "Prevention and Therapy of Scarlet Fever."—Among others, John I. Nurnberger spoke before the Chicago Pathological Society, November 10, on "Method for Determining the Viscosity of Venous Blood."

INDIANA

A Veteran County Secretary.—The *Journal* of the Indiana State Medical Association for November comments on the many years of service of Dr. Wilson T. Lawson, Danville, as secretary of the Hendricks County Medical Society. Dr. Lawson has served continuously in this capacity since 1879 with the exception of three years when he was president of the society.

Board of Registration in Medicine.—Dr. Hugh W. Eikenberry, Peru, has been named a member of the state board of registration in medicine, succeeding Dr. James M. Hicks Jr., Huntington, and Clarence F. Aumann, D.C., Indianapolis, succeeding Harry K. McIlroy, D.C., Indianapolis. Members who were reappointed are Dr. Norris E. Harold, Indianapolis; Dr. Jesse W. Bowers, Fort Wayne; Dr. Hobart C. Ruddick, Evansville, and Clarence B. Blakeslee, D.O., Indianapolis.

LOUISIANA

Society News.—Dr. Charles J. Bloom, New Orleans, addressed the Tangipahoa Parish Medical Society, recently, in Hammond on "Recent Advances in Pediatrics."—The Orleans Parish Medical Society was addressed in New Orleans, October 13, by Drs. Howard R. Mahorner, New Orleans, on "Sympathetic Nerve Block in Rehabilitation of the Injured Extremity" (Case Report).

Award to Dr. Matas.—Dr. Rudolph Matas, since 1928 professor of general and clinical surgery, emeritus, Tulane University of Louisiana School of Medicine, New Orleans, was presented with the Times-Picayune Loving Cup for 1940, October 25, "in recognition of his years of unselfish service to his fellowman." Leonard K. Nicholson, president of the *Times-Picayune* and the *New Orleans States*, made the presentation and Dr. Maxwell E. Lapham, dean of the medical school and W. R. Irby professor of obstetrics, presided. A luncheon followed the ceremony, which was held in the auditorium of the Hutchinson Memorial Building as a part of the "home coming" program. Dr. Matas is the third physician to receive the award since it was established in 1901, the other two being Dr. Arthur W. De Roaldes in 1905 and Dr. Sara T. Mayo in 1910.

MAINE

Society News.—The New England Society of Psychiatry was addressed at its regular fall meeting in Augusta, October 17, by Major Donald E. Currier of the Massachusetts National Guard, Wenham, and chief of the medical division, Massachusetts Selective Service System, Boston, on "Medical and Psychiatric Features of the Selective Service Program."—Dr. Clarence Wesley Sewall, Boston, discussed "Eclampsia" before the Kennebec County Medical Association in Gardiner September 18.—Dr. Frederick T. Hill, Waterville, addressed the Piscataquis County Medical Association in Dover-Foxcroft, September 18, on postgraduate education.

MARYLAND

Personal.—Dr. William Ross Cameron, Baltimore, on September 13 was commissioned senior surgeon in the U. S. Public Health Service for duty as regional medical officer of the Third Civilian Defense Area. Dr. Cameron served for many years as public health administrator in Alabama and West Virginia and with the Maryland State Department of Public Health.—Dr. George W. Corner, director of the department of embryology of the Carnegie Institution of Washington at Baltimore, has been elected a foreign corresponding member of the National Academy of Medicine of Argentina.

Dr. McCollum to Deliver Harben Lectures in Canada.—Elmer V. McCollum, Sc.D., professor of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, will deliver the Harben Lectures of the Royal Institute of Public Health and Hygiene of London, England, for 1941. Because of war conditions, the University of Toronto has been designated for the delivery of the lectures December 1-3. Dr. McCollum will discuss "Nutritional Science and Public Health." The separate titles of the lectures are "Inorganic Elements Which Present Nutrition Problems of Practical Importance," "Problems Presented by the Availability of Low-Cost Synthetic Vitamins—Enrichment, Fortification and Restoration of Refined Foods" and "Nutrition Problems Presented by Low Income Families."

MINNESOTA

Society News.—The Minnesota Society of Neurology and Psychiatry was addressed in St. Paul, September 9, by Drs. Philip H. Heersema, Rochester, on "Symptomatic Treatment of Hysteria" and Alex Blumstein and Carl M. Eklund, Minneapolis, "Equine Encephalitis in the Human."—The Wabasha County Medical Society was addressed in Wabasha, October 9, by Drs. Donald G. Mahle, Plainview, who gave his presidential address on undulant fever; Edward N. Cook, Rochester, Minn., enuresis; Thomas G. Wellman, Lake City, "Ligation in Treatment of Varicose Veins," and Victor F. J. Bruder, Winona, "Carcinoma of the Cervix."—Dr. John R. Meade, St. Paul, discussed diabetes before the Washington County Medical Society, September 9, in Stillwater.

Annual Session of Medical Foundation.—An annual meeting of the Minnesota Medical Foundation was held in the University of Minnesota Union, Minneapolis, November 7, with Dr. Erling S. Platou, Minneapolis, president, presiding. According to a report of the treasurer, Dr. Jennings C. Litzenberg, Minneapolis, the organization now has available more than \$40,000 to be used in making grants for research, lectureships and in other ways promoting the interests of medical education in the University of Minnesota. Dr. Morris Fishbein, Editor of *THE JOURNAL*, spoke on "Medicine in the Emergency." The *Bulletin* of the Minnesota Medical Foundation appeared in November in a new form under the title "Trends in Medical Practice and Research," containing abstracts of recent contributions by members of the faculty and a number of original articles on various subjects.

MISSOURI

Biennial Registration of Physicians Due by December 31.—Every person licensed to practice medicine and surgery in Missouri must register biennially, in odd numbered years, on or before December 31 with the state board of health and at that time pay a fee of \$1. If such a person fails to register timely, the required fee plus 50 cents for each month or part thereof of delinquency must be paid to the board. In addition, a person who practices without registering timely may be subjected to a fine of not more than \$500 or imprisonment up to six months, or both, for each day of practice without such registering.

NEW MEXICO

Plague Infection.—*Public Health Reports* announces that plague infection was found in a pool of 147 fleas collected from 59 *Cynomys gunnisoni zuniensis* prairie dogs shot at locations southwest of Ramah, Valencia County, and in another pool of 188 fleas from 29 prairie dogs of the same species shot in a location east of Ramah on September 9.

NEW YORK

Professor of Hygiene and Public Health.—Dr. William T. Clark, associate professor of hygiene and public health at the University of Buffalo School of Medicine, Buffalo, has been appointed professor and head of the department of hygiene and public health to succeed the late Dr. Walter S. Goodale. The latter had held the position for sixteen years prior to his death, October 8, and just a few days before had been made professor emeritus, newspapers reported. Dr. Clark has also been appointed superintendent of the Edward J. Meyer Memorial Hospital, a city institution, where he has been a member of the staff. This position was also held by Dr. Goodale at the time of his death. Dr. Clark graduated at the University of Buffalo School of Medicine in 1925 and received his degree in public health from Johns Hopkins University, Baltimore, in 1937.

New York City

The Harvey Lecture.—Dr. Thomas Francis Jr., professor of epidemiology, School of Public Health, University of Michigan, Ann Arbor, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine, November 27, on "Factors Conditioning Resistance to Epidemic Influenza."

Appointed to Palestine Hospital Staff.—Dr. Henry Wigderson, an instructor in surgery (neurosurgery) at New York University College of Medicine and a member of the staffs of several hospitals, has been appointed head neurosurgeon in the Rothschild-Hadassah-University Hospital at the medical center on Mount Scopus, near Jerusalem. He graduated at the University of Maryland School of Medicine, Baltimore, in 1931. With his wife, he was to leave for Palestine on October 24.

Dinner Marks Expansion of Birth Control Movement.—A dinner was held at the Hotel Roosevelt, October 16, to observe the founding of the first birth control clinic by Mrs. Margaret Sanger, and simultaneously throughout the country twenty-six meetings convened to commemorate the event. The national observance was under the auspices of the Birth Control Federation of America, the National Committee for Planned Parenthood and other civic groups, the *New York Times* reported. As part of the national celebration it was announced that there are now six hundred and twenty-five clinics, of which one hundred and ninety-two are located in public health quarters, now in operation in the country.

Appointments at Columbia.—Appointments recently announced by Columbia University for 1941-1942 include the following:

Dr. Charles C. Wilson, Hartford, Conn., professor of health and physical education at Teachers College.

Drs. David Ulmar, assistant clinical professor of medicine, and Gerald H. Pratt, assistant clinical professor of surgery, in the New York Post-Graduate Medical School and Hospital.

Drs. Frederick A. Mettler, associate professor of anatomy, and Alson E. Braley, assistant professor of ophthalmology in the College of Physicians and Surgeons.

Drs. Myron E. Wegman, assistant professor of child hygiene, and Oscar G. Costa Mandry, assistant professor of tropical medicine in the School of Tropical Medicine of the University of Puerto Rico under the auspices of Columbia in San Juan, P. R.

OHIO

Postgraduate Lectures.—The Ohio State Medical Association resumed its five year program of postgraduate lectures on November 5, when it opened a series in McConnsville. Other series were started in Dennison on November 6, Ashland on November 7, Springfield on November 12 and Piketon on November 13. The subjects included treatment of burns, chemotherapy, treatment of nephritis, deficiency diseases seen as complications of common medical conditions and control of obstetric hazards.

OREGON

Annual Registration Due December 1.—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to register annually on or before December 1, with the secretary of the board of medical examiners, and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days, or part thereof, of default, and his failure to reregister within ninety days after December 1 is a misdemeanor.

Society News.—Drs. Howard C. Naffziger and Harry Glenn Bell, San Francisco, addressed the Central Willamette Medical Society in Corvallis October 2. Dr. Naffziger spoke on "Disability in the Upper Extremities from the Scalene Syndrome," "Causes of Back Pain and Sciatica" and "Needs of National Defense." Dr. Bell discussed "Lesions of the Small Bowel" and "Use of Sulfanilamide and Related Compounds in the Treatment of Lesions of the Colon."—Drs. Leo S. Lucas, Harry C. Blair and Gilbert J. McKelvey, Portland, discussed "Disabilities and Fractures of the Knee Joint" and Dr. John E. Raaf, Portland, "Indian Medicine and the Medicine Man" at a meeting of the Multnomah County Medical Society, Portland, October 1.

PENNSYLVANIA

Personal.—Dr. Edgar S. Buyers, Norristown, who has retired after thirteen years' service as trustee and council of the Second Council District, was presented by the membership with a bronze plaque.

Infantile Paralysis in Collingdale.—Five public and parochial schools in Collingdale, Delaware County, were closed on October 29 when 1 case of infantile paralysis was discovered in the borough, newspapers reported. The case was the first in Collingdale this year. Another new case was discovered in Ardmore.

Society News.—Dr. Moacyr E. Alvaro, São Paulo, Brazil, addressed the Reading Society of Ophthalmology and Otolaryngology, October 30, on "Pan American Ophthalmology."

—A symposium on infantile paralysis was presented before the Westmoreland County Medical Society in Latrobe, November 4, by Drs. Edmund R. McCluskey and James O. Wallace, both of Pittsburgh.

Philadelphia

Meeting of Ex-Residents.—The fifty-fifth annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held on December 2 at the Midway Club, Fidelity-Philadelphia Building. Dr. James W. McConnell will be the guest of honor, and Dr. Russell S. Boles, president of the association, will preside and serve as toastmaster.

First Pancoast Memorial Lecture.—Dr. George W. Holmes, clinical professor of roentgenology, Harvard Medical School, Boston, delivered the first Pancoast Memorial Lecture, November 6, under the auspices of the Philadelphia Roentgen Ray Society, on "Roentgen Diagnosis and Treatment of Primary Pulmonary Neoplasm." At the time of Dr. Henry K. Pancoast's death on May 20, 1939 he was professor of radiology at the University of Pennsylvania School of Medicine and the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania.

RHODE ISLAND

New Medical Board.—Thomas B. Casey, Providence, chief of the division of examiners, announces that a new board of examiners in medicine has been appointed for Rhode Island: Dr. Joseph C. O'Connell, Providence, chairman; Dr. John A. Bolster, Providence, secretary, and Dr. Earl F. Kelly, Pawtucket.

Society News.—A panel discussion on vitamins was presented before the Providence Medical Association, October 6, by Drs. Frank J. Jacobson, William P. Buffum, Banice Feinberg, Harold G. Calder and Reuben C. Bates. All are from Providence. The association devoted its meeting November 3 to a symposium on "The Neuropsychiatric Study of the Naval Recruits." Members of the U. S. Naval Training Station, Newport, participated. Dr. James W. Sever, Boston, discussed "Colles Fractures, a Study of Pre and Post Reduction X-Rays."

TENNESSEE

Changes in Health Personnel.—Dr. Robert E. Rock, Opelika, Ala., who recently succeeded Dr. Alex B. Shipley, Elizabethton, as health director of Carter, Unicoi and Johnson counties, has been appointed associate director of venereal disease control of the state. Dr. Shipley will direct the health unit until the position has been filled.—Dr. Howard C. Stewart has been named director of the Williamson County Tuberculosis Study, Franklin, a position he formerly held until he resigned in September 1938 to become associated with the health department of Cleveland, Ohio. Dr. Stewart succeeds Dr. William J. Murphy, Franklin, who has joined the staff of the Georgia State Department of Health with offices in Decatur.

VERMONT

Dr. Beecher Appointed Dean at Vermont.—Dr. Clarence H. Beecher, professor of medicine at the University of Vermont College of Medicine, Burlington, has been appointed dean of the school to succeed Dr. Hardy A. Kemp, who has assumed a similar position at Ohio State University College of Medicine, Columbus. Dr. Beecher was born in Granville, N. Y., in 1877. He graduated at the Vermont school of medicine in 1903, serving there as instructor and demonstrator in anatomy from 1901 to 1906, instructor in medicine, 1905-1909, and assistant professor of medicine from 1909 to 1911, when he became professor. At one time he served as secretary and president of the Vermont State Medical Society.

VIRGINIA

State Medical Election.—Dr. John M. Emmett, Richmond, was named president-elect of the Medical Society of Virginia at its meeting in Virginia Beach, October 7, and Dr. Roshier W. Miller, Richmond, was inducted into the presidency. Vice presidents of the society are Drs. James W. Anderson, Norfolk, Ernest G. Scott, Lynchburg, and James P. Williams, Richlands. Miss Agnes V. Edwards, Richmond, was reelected secretary. Roanoke was chosen as the place of the annual session next year.

WASHINGTON

Society News.—A symposium on venereal disease was presented before the Pierce County Medical Society, Tacoma, October 14, by Drs. Homer W. Humiston, Leland E. Powers and Carlisle Dietrich, and MacBroom Benjamin, captain, M. C., U. S. Army, Fort Lewis, discussed "The Physician's Role in Tacoma's Home Defense."—Drs. Ralph M. L. Dodson, Portland, Ore., and John A. Kahl, Walla Walla, addressed the Walla Walla Valley Medical Society, Walla Walla, October 9, on "Preparedness from the Surgical Viewpoint" and "Preparedness from the Public Health Viewpoint" respectively.—Drs. James M. Bowers and Robert E. Mullarky, Seattle, addressed the King County Medical Society, Seattle, October 20, on "Pulmonary Emboli: Report of a Fatal Medical Case" and "Indications and Value of Peritoneoscopy" respectively. Dr. Robert D. Forbes, Seattle, discussed a case of bullet wound of the abdomen.

GENERAL

The American Woman and Her Responsibilities.—A forum on "The American Woman and Her Responsibilities" was held at Stephens College, Columbia, Mo., November 6-8. The discussion aimed to clarify the responsibilities of women in a democracy and sought a program for giving effective direction to their role as the primary force in shaping the ideals, strengths and moral fiber of a nation. Speakers of national prominence in various fields were on the program.

New Secretary of Lepers Mission.—Dr. Eugene R. Kellersberger recently returned from Bibanga, Belgian Congo, to accept an appointment as executive secretary of the American Mission to Lepers. The group held its thirty-fourth annual meeting in New York, October 9-11, with the theme devoted to "Freedom for All—from Leprosy." William Jay Schiefelin, Ph.D., presided and Dr. Kellersberger spoke on "Leprosy in the East." Dr. Kellersberger graduated at Washington University School of Medicine, St. Louis, in 1915. He has served as a medical missionary for twenty-four years in the Belgian Congo, the New York Times reported. It was announced at the session that \$293,672 had been received from 41,000 persons during the fiscal year ended June 30, the largest sum ever received by the group in any one year.

Mead Johnson Prizes.—René J. Dubos, Ph.D., of the Rockefeller Institute for Medical Research, New York, and Dr. Albert B. Sabin, associate professor of pediatrics, University of Cincinnati College of Medicine, Cincinnati, were named recipients of the E. Mead Johnson Awards by the American Academy of Pediatrics during its annual meeting in Boston, October 10. Dr. Dubos received the first award of \$500 for his work leading to the development of gramicidin, useful in the treatment of diseases caused by pathogenic bacteria, and Dr. Sabin the second award of \$300 for research in diseases of the nervous system caused by viruses. The academy chose Dr. Borden S. Veeder, St. Louis, as president-elect and inducted Dr. Edward C. Mitchell, Memphis, into the presidency. Dr. Clifford G. Grulee, Evanston, Ill., was reelected secretary. The 1942 session of the academy will be in Chicago, the dates to be announced later.

Federation Proceedings.—In March 1942 the Federation of American Societies for Experimental Biology will issue the first number of a quarterly publication to be named the *Federation Proceedings*, which will be published by an editorial board representing the five constituent societies: American Physiological Society, American Society of Biological Chemists, American Society for Pharmacology and Experimental Therapeutics, American Society for Experimental Pathology and the American Institute of Nutrition. In the past each society has printed its own abstracts in advance of the annual meeting in a separate pamphlet. After the meeting the abstracts were republished in permanent form in the journals of the various societies. In the future a single publication will suffice and abstracts of all the societies will be available in a single volume. The Yearbook will be discontinued. The *Federation Proceedings* will be distributed without charge to the one thousand seven hundred members of the federation. The subscription price will be \$4 to nonmembers. Subscriptions and other communications concerning advertising space should be addressed to Dr. Donald R. Hooker, managing editor, 19 West Chase Street, Baltimore.

Public Health Meeting.—Dr. Allen W. Freeman, Baltimore, was named president-elect of the American Public Health Association at the annual session in Atlantic City, October 16, and Dr. John L. Rice, New York, was inducted into the presidency. Other officers are Drs. Donald T. Fraser, Toronto; Eduardo Garrido-Morales, San Juan, P. R., and Pearl McIver, R.N., Washington, D. C., vice presidents; Louis I. Dublin, Ph.D., New York, treasurer, and Dr. Reginald M. Atwater, New York, executive secretary. The 1942 session will be held in St. Louis. A special session was held during the meeting to hear three representatives of the British Ministry of Health: Sir John B. Orr, director of Rowett Research Institute, Aberdeen, Scotland; Sir William Wilson Jameson, chief medical officer of the Ministry of Health, London, England, and Dr. James M. Mackintosh, professor of public health, University of Glasgow, Scotland. At a luncheon session on public health in American defense, Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service, retired, Washington, D. C., was presented with a scroll. The presentation was made by Dr. Hugh d'Amato, secretary of the National Department of Health of Argentina on behalf of the Pan American Sanitary Bureau.

Hearing on Identity of Oleomargarine Denied.—Federal Security Administrator Paul V. McNutt announced October 31 that he had notified Ralph E. Ammon, director of the State Department of Agriculture, Madison, Wis., that "it's in

the public interest" to deny the petition of the United Dairy Committee for a rehearing on the standard of identity for oleomargarine established by the Federal Security Agency. The United Dairy Committee, composed of farmers of many of the dairy states and headed by Mr. Ammon, conferred with Mr. McNutt, September 24, and appealed for a rehearing on the entire standard and particularly requested a reexamination of the legal basis for the inclusion of diacetyl as a flavoring ingredient in oleomargarine. This standard became effective on Sept. 5, 1941, following a hearing held in November 1940. After conferring with the Federal Security Agency's legal staff, the administrator said he had been advised that on the evidence already in the record there is no legal basis on which he could prohibit the use of diacetyl in oleomargarine under the authority of the Food, Drug and Cosmetic Act. Mr. McNutt pointed out that basically the definition issued for oleomargarine goes back to that contained in the oleomargarine tax law of 1886, in which Congress recognized oleomargarine as a product made in imitation of butter and imposed specific taxes on its manufacture and sale. He explained that the law authorizes the establishment of definitions and standards for foods when these will promote honesty and fair dealing in the interest of consumers. He contended that the recall of the definition and standard for oleomargarine would result in the removal of necessary protection to the buying public.

Radiological Society of North America.—The twenty-seventh annual meeting of the Radiological Society of North America will be held at the Hotel Fairmont, San Francisco, December 1-5, under the presidency of Dr. William Walter Wasson, Denver. Among the papers listed in the preliminary program are the following:

Dr. Edwin B. Boldrey, San Francisco, Pathology of Brain Tumors and Its Relation to Roentgenologic Diagnosis.

Dr. John D. Camp, Rochester, Minn., Intracranial Calcification of Non-Neoplastic Origin.

Dr. Albert K. Merchant, Stockton, Calif., Roentgen Diagnosis of Fungus Infections of the Intestinal Tract.

Dr. Ernst A. Pohle, Madison, Wis., Roentgen Therapy in Cancer of the Breast: An Analysis of Our Experience at the State of Wisconsin General Hospital During the Last Twelve Years.

Dr. James P. Rousseau, Winston-Salem, N. C., The Value of Roentgen Therapy in the Treatment of Pneumonia Which Fails to Respond to Sulfonamide Therapy.

Paul C. Aebersold, Ph.D., San Francisco, The Cyclotron and Nuclear Physics.

Dr. John H. Lawrence, San Francisco, Artificial Radioactive Elements in the Treatment of Disease.

Dr. Hymer L. Friedell, New York, Bone Lesions in Hodgkin's Disease. Medical Director Arthur H. Dearing, captain, U. S. Navy, Mare Island, Calif., The Specialist as a Medical Naval Officer.

Gioacchino Failla, Sc.D., New York, Influence of the Medium on the Radiosensitivity of Sperm.

The annual Carman Lecture will be delivered, December 2, by Dr. William Edward Chamberlain, Philadelphia, on "Fluoroscopes and Fluoroscopy."

HAWAII

Personal.—Dr. William M. Shanahan, formerly of Milwaukee, has been appointed assistant psychiatrist to the mental health clinic at Queen's Hospital, Honolulu. —Dr. Charles L. Wilbur Jr., formerly of Philadelphia, has returned to his position as director of the bureau of maternal and child health of Hawaii after a year's study at the Children's Hospital, Cincinnati. —Dr. Frederick K. Lam, Honolulu, was recently appointed general chairman of the United China Relief, Inc., for the Territory of Hawaii.

Territorial Association Publishes Journal.—The *Hawaii Medical Journal* made its appearance with the September issue. It is published by the Hawaii Territorial Medical Association with Dr. Lyle G. Phillips, Honolulu, as editorial director; Dr. Harry L. Arnold Jr., Honolulu, editor, and Miss Elizabeth D. Bolles, Honolulu, secretary and business manager. The initial issue contains papers presented before the fifty-first annual meeting of the association in May. Sections are devoted to "Plantation News," "Medical Preparedness" and "Notes and News." This year it is planned that each county medical society be responsible for one issue of the *Journal*. The November issue will be arranged for by the Honolulu County Medical Association, the January issue by the Hawaii County association, the March issue by the Maui County society and the May issue by the Kauai County society.

FOREIGN

Free Medical Care in New Zealand.—The House of Representatives, Wellington, New Zealand, on October 4 passed a measure creating a system of free medical care beginning November 1, according to the *New York Times*. The measure as adopted permits physicians to practice without direct payment by the state but without the right to collect unpaid fees through the courts. The *Times* reported that some gov-

ernment leaders fear the concessions will lead to high fees, while the patient may recover not more than the equivalent of \$1.50 a visit from the social security fund. Under its original plans the government intended to fix fees for physicians at the equivalent of \$1 for advice at offices and \$1.30 for visits to patients' homes. As a concession to the profession, which threatened to defy the government, the prices were changed to \$1.50 in both cases. Patients may now, under the amended measure, pay the physician and later get the money from the social security fund. This plan, under which the patient and not the physician receives the money, was adopted to make the maternity bonus acceptable to the physicians and permit them to be independent of the state, the *Times* reported. Finance Minister Walter Nash assured the House of Representatives on October 8 that funds were available for operation of the free medical care plan beginning November 1. The *Times* reported October 26 that Dr. Sidney D. Rhind, national secretary of the Medical Association, had announced the physicians' defiance of the government. He said doctors would attend patients at the old fees, leaving the patients to obtain from the social security fund what they could. He said further that the government had no contracts with the doctors and that physicians would not cooperate in administering the plan until their rights to go to the courts to collect unpaid fees were restored.

Government Services

Report of Surgeon General of the Navy

According to the annual report of the Surgeon General of the Navy, there were 314 deaths from all causes in 1939, giving a rate of 2.10 per thousand as compared with 2.60 for the preceding year. There were 50 deaths, including 1 suicide, caused by motor vehicle accidents. There were 42 instances of suicide and attempted suicide reported in 1939, resulting in 32 deaths. There were 4 deaths from homicide. Diseases with 127 deaths, injuries with 181 deaths, and poisonings with 6 deaths were responsible for 40.45, 57.64 and 1.91 per cent, respectively, of all deaths. There were 1,201,718 sick days from all causes in 1939, an average of 8.03 sick days per person and 19.67 per admission. There were 22.01 per cent of all personnel constantly on the sick list throughout the year. One thousand five hundred and fifty-two persons were invalided from the service as the result of physical disability in 1939, giving a rate of 10.37 per thousand as compared with 10.59 for the preceding year and 12.23, the median for the preceding nine year period. Diseases caused the invaliding of 115 officers of the navy, 23 officers of the marine corps, 840 enlisted men of the navy, 343 enlisted men of the marine corps, 99 midshipmen and 17 nurses. Injuries caused the invaliding of 10 officers of the navy, no officers of the marine corps, 66 enlisted men of the navy, 35 enlisted men of the marine corps, 4 midshipmen and no nurses. The disability was reported as existing prior to entry into the naval service in 635 cases, of which 617 were for disease and 18 for injury. In addition to 873,433 treatment days at naval hospitals there were 42,875 days for 2,042 patients on the hospital ship U. S. S. *Relief*; 3,848 days for 27 tuberculosis patients at the naval unit, Fitzsimons General Hospital, U. S. Army, Denver, and 15,975 days for 155 insane patients at the Naval Unit, St. Elizabeth's Hospital, Washington, D. C. The 12,847 admissions for venereal diseases gave a rate of 85.7 per thousand in 1939 as compared with 77.45 for the preceding year and 90.28 the median for the preceding nine year period. In 1937 action was taken to remove punitive measures imposed on enlisted men for venereal disease and 1938 was the first full year in which the effect of this step could be observed. The 1938 to 1939 increase in venereal disease incidence is 5.13 per thousand less than that of 1937 to 1938 and may reflect an additional breakdown of the attitude toward concealment of venereal disease and fear of punitive action. The report indicates that the health of the navy was good during 1939 and attributes in part the slight increase in the general admission rate over the preceding year to the induction of large numbers of recruits during the last five months of the year. The number of recruits finally accepted in the navy and marine corps was 33,312, which constituted 25.0 per cent of the average daily enlisted strength, as compared with 15.4 per cent in 1938.

One major disaster occurred in 1939 when the submarine U. S. S. *Squalus* sank off the Isle of Shoals (Portsmouth, N. H.). Twenty-three enlisted men and 1 officer lost their lives by drowning; 32 members of the crew were rescued by means of the diving bell.

The Need for Biology in Education

In an address to the British Social Hygiene Council on "Biology and Health," Sir Walter Langdon-Brown referred to the blight which had fallen on European culture, the hapless condition of university life and the subservience of scientific work to the Nazi system. The *Münchener medizinische Wochenschrift*, formerly one of the leading medical journals of the world, had become scientifically negligible and the happy hunting ground of naturopaths and other cranks who happened to catch the Fuehrer's eye. The fate of Pflügers *Archiv für die gesamte Physiologie des Menschen und der Tiere*, for more than seventy years the leading publication of physiologic and biologic research, was also significant. In 1932, the last pre-hitlerian year, it ran to five volumes; in 1938 it was one slim volume of articles mainly written by Japanese and Russians.

Biology impressed on the mind the idea of progress as the increasing complexity and adaptations of animal life were studied. If this study had been pursued with the same intensity as that of physics and chemistry, men might have become so interested in the wonderful processes of life that they would not have been so keen on inflicting death. The general public would have no adequate grasp of the principles of social hygiene until they had some idea of biologic principles. Turning to the problem of venereal disease, in which the British Social Hygiene Council is especially interested, Langdon-Brown suggested that perhaps the romanticizing tendency of the English made them unwilling to face the uncomfortable fact that behind the mystery of the continuity of life lurked the shadows responsible for venereal disease. But it was mainly ignorance of biology that was responsible for failure to realize the natural law that whenever the continuity of life was threatened the impulse to create more life was increased. There had been no sensational rise in the incidence of venereal disease in this war, as there had been in the last. But this was no reason for relaxing the efforts of the British Social Hygiene Council in dealing with the problem of venereal disease.

The Milk Supply

Among the food problems created by the war, the milk supply is one of the most important. The minister of health has made an encouraging report on the prospect for the coming winter. In the last prewar year our consumption was 70 million gallons a month. The minister estimates that the amount available in the worst month of the coming winter will be between 70 and 80 million gallons. Though greater than the prewar amount there is still a problem, as the diminished importation of milk powder and condensed milk has increased the demand for fresh milk. With some difficulty the minister has been restricting consumption to put milk into reserve for the winter in the condensed form. Condensed milk and milk powder equal to 150 million gallons of liquid milk is expected to be available, allowing a supply of 25 millions a month and bringing the total supply up to 100 millions a month, considerably in excess of any consumption that this country has known heretofore.

The supply of milk is controlled so that those with the greatest need shall have first call. Expectant mothers and babies up to the age of 5 years will get a pint daily; children up to 17 half a pint daily in addition to the amount they receive in the schools. Invalids according to their necessities will obtain up to 2 pints daily. It cannot be assumed that we could give these priorities and go on with unrestricted use of milk elsewhere. Last winter children were short of milk in

some parts of the country. The minister is therefore asking the fighting services to take much larger quantities of condensed milk, which is particularly suited for their use. A limit will be put on the quantities of liquid milk that can be supplied to catering establishments. They will be given condensed milk and milk powder, which they can use for cooking. For the preparation of meals in schools, milk powder will be used. There will be ample quantities of condensed milk to meet the reasonable needs of every section of the people. It is estimated that a family of six with two children under 5 and two under 17 will be able to get 25 pints of liquid milk weekly, excluding the amount obtained at school. In a small family with one child under 3, 11 pints will be available weekly. Two adults will probably get 4 pints weekly. In addition to all this, supplies of condensed milk will be available when the winter supply of liquid milk is at its lowest. This should be equal to about a further 3 pints of liquid milk a family per week. These represent the minimum figures.

Injuries of the Locomotor System

The war has produced a need for more surgeons with training and experience in the diagnosis and treatment of injuries of the locomotor system. Arrangements have therefore been made for instructional courses extending over six weeks. The surgeons attending the courses will be divided into groups of not more than four, which will be attached to the wards and outpatient department of a senior surgeon experienced in this work. They will have charge of cases, carry out treatment and receive practical demonstrations. They will also do the work and teaching of neighboring hospitals, fracture departments and clinics. The first course will begin at Liverpool, the city which inherits the great orthopedic traditions of Thomas and of Jones. The courses will be conducted by such well known orthopedic surgeons as R. Watson-Jones, T. P. McMurray, B. L. McFarland, F. C. Dwyer, G. E. Thomas and W. R. Mitchell. This course is designed for surgical specialists both in the fighting services and in the emergency medical service (for civilian casualties). The number of entries will be limited to sixteen, for whom accommodation will be arranged in the neighborhood of one of the hospitals.

Norwegian Hospital in London

A Norwegian hospital for the men of the Norwegian Navy and Merchant Service has been in existence for about a year. It has forty-five beds, of which forty are at present occupied. It is staffed entirely by Norwegian physicians and nurses, and the members of the staffs are mainly Norwegian ex-service men. The hospital was inspected by the crown prince of Norway, Prince Olaf, who talked with seamen who served in the Lofoten raid.

Control of Tuberculosis in Argentina

The recently formed Comisión Nacional de la Tuberculosis consists of a president, vice president, general secretary and four members, all in office for a term of six years. This commission is to take over the technical and administrative direction of all tuberculosis hospitals, sanatoriums and similar institutes supported with state funds and the technical direction and the administrative control of private institutes subsidized by the state. The commission will erect eighteen city hospitals and twelve rural sanatoriums in various regions; these had already been provided for by the law in question but had not been erected as yet. Further tasks are the erection of schools for the training of personnel, the compilation of statistics, the arrangement of meetings and lectures, education of the public, control of mutual aid societies and the supervision of medications. The commission is to concern itself also with the obligation of reporting cases of tuberculosis and with special

tion. The establishment of provincial and territorial subcommissions is provided for. Prophylactic measures are also to be taken. Organizations that are concerned with the campaign against tuberculosis cannot be founded without approval of the *Comisión Nacional*.

To begin the examination of the population for tuberculosis, the government of Argentina has issued a decree which obliges all government employees, officials and workers to submit to periodic examination for tuberculosis. Those found to be tuberculous are to receive the leave of absence provided for in an earlier decree, and admission to the large tuberculous hospital "Hospital Nacional Central."

The annual report on the campaign against tuberculosis in Buenos Aires appeared recently. The municipal organization is concerned not only with the hospital and polyclinic treatment, obstetric care for tuberculous women, isolation of the children of tuberculous parents, support of colonies at the seashore and detection of undiscovered cases of tuberculosis but also with the therapeutic, prophylactic and social side of the problem. Although the mortality has been reduced, tuberculosis is still a problem for which neither the available public nor private means are adequate. The number of beds is insufficient to care for all tuberculous patients who are in need of institutional care. According to reports, the five thousand beds available in the tuberculosis hospitals in Buenos Aires and various regions of the country do not meet one third of the requirements.

The sensational press of Buenos Aires has been concerned for months with a new tuberculosis vaccine developed by one Jesús Pueyo. This man is a student aged 40, a Spaniard, who for a time was an assistant at the microbiologic institute. He asserts that he developed a vaccine with curative and prophylactic properties against tuberculosis. The faculty of Buenos Aires was willing to perform an investigation, but Pueyo refused. He demanded that his vaccine be used first for the treatment of human subjects, whereas the investigating commission wanted to begin with an experimental examination. The further course was the following: Pueyo appealed to the minister of the interior, who suggested an examination in the bacteriologic institute of the Departamento Nacional de Higiene with special concessions for Pueyo, but here again Pueyo made impossible demands. Pueyo now attempts further distribution and application of his vaccine, although he knows that legal regulations prohibit this; the president of the Departamento Nacional de Higiene, on the basis of existing laws, has now decreed a fine of 1,000 pesos. The minister of the interior had previously ruled that Pueyo could use his vaccine for scientific research but not for public distribution. The case was discussed also in the Argentine parliament. It was pointed out that the behavior of Pueyo had created an unfavorable impression. The same critical stand was taken by a medical commission appointed by the ministry for public health in Uruguay. On the basis of the available evidence and of former experiences with such preparations, the Pueyo case may be regarded as closed as far as science is concerned.

Campaign Against Trachoma in Argentina

Dr. José A. Cená, chief of the section on trachoma of the Departamento Nacional de Higiene, has issued a report on the campaign against trachoma in Argentina. Trachoma became particularly serious after the eighth decade of the last century. Although in Buenos Aires the spread of trachoma has been so effectively counteracted that the capital is now practically free from it, trachoma is still on the increase in the interior. After extensive observations an investigating committee was appointed in 1923 and a section for the prophylaxis of trachoma and infectious eye diseases was founded at the beginning of 1924 in the Departamento Nacional de Higiene. Dispensaries were opened, but their activity was rather restricted owing to lack of funds. In 1927 the ophthalmologist Prof. Ernst Fuchs made

a tour of investigation and ascertained that in spite of expressed doubts the existing disorder was true trachoma. Since 1935 the campaign against trachoma has been intensified and has been carried into the schools; the school children are examined for trachoma and if necessary are treated. Sulfanilamide has recently been used with considerable success for this purpose.

Health Organizations in Paraguay

The health conditions of Paraguay were recently presented in an official report. The organization of public health matters in Paraguay began with the formation of the national hygienic council (*Consejo Nacional de Higiene*) in 1889. Regulations regarding the practice of medicine have existed since 1900. The national commission for public aid and social welfare was founded in 1915 when the *Consejo Nacional de Higiene* was converted into the Bureau for public health matters. In 1917 the two were combined under the name *Departamento de Higiene y Asistencia Pública*. This organization existed until 1936, when the ministry for public health was established. This ministry has five departments: *Asistencia Pública* in the capital, rural hygiene, hygiene in general, child welfare and dentistry. At the request of the government the ministry was reorganized in 1940 by Dr. Henry Hanson, member of the *Oficina Sanitaria Panamericana*.

The most important medical problem in Paraguay is infant mortality. To counteract the extreme undernourishment of children, particularly in rural regions, 15 per cent of the rural taxes have been allotted for feeding children in the schools, an arrangement already carried out in eighty localities.

Leprosy is the second important problem. Abdominal typhoid and other forms of typhoid will be more effectively counteracted when Asunción and other large cities have been equipped with proper sewerage systems. Vaccination against typhoid is obligatory for school children. Malaria became a national catastrophe in 1940; fourteen commissions were established, which distributed more than 500,000 quinine tablets and other preparations. About 30,000 patients were treated. Petroleum was used to eradicate the breeding grounds. *Ancylostomiasis* is likewise widely disseminated. The tuberculosis mortality is relatively high, although it has somewhat decreased in recent years; however, the tuberculosis morbidity has increased.

In the rural hospitals, special departments are to be established for infants. Of 4,700 children in the capital, 4.8 per cent were found to have trachoma.

Brief Reports

The bacteriologic institute of the Departamento Nacional de Higiene in Buenos Aires celebrated its twenty-fifth anniversary in June; since then it has borne the name of its founder, Dr. Carlos J. Malbrán. Several new laboratories were opened at the time of the celebration.

During July a number of Argentinian physicians visited the university of Rio de Janeiro. At the same time Rio de Janeiro had an exhibit of paintings, sculptures and photographs created by Argentinian physicians. A library of Argentinian medical authors, selected by Dr. Juan Ramón Beltrán, professor of history of medicine at the university of Buenos Aires, was presented to Getulio Vargas, the president of Brazil.

The seventh Congreso Nacional de Medicina, which will be held in La Plata in 1943, will have as its subjects rheumatism and arterial hypertension.

James Ewing of New York held conferences on malignant neoplasms at the invitation of the faculty of medicine of Rosario and also in Buenos Aires. From Buenos Aires he went to Santiago, Chile.

Prof. Ernest Carroll Faust, parasitologist of Tulane university, at the invitation of the faculty of medicine of Buenos Aires, recently held a number of conferences on his specialty.

A recent art exhibit in Buenos Aires presented paintings and pieces of sculpture created by physicians.

Deaths

James Norment Baker * Montgomery, Ala.; University of Virginia Department of Medicine, Charlottesville, 1898; secretary of the Alabama State Board of Censors and state health officer; in 1934 elected to the executive committee and in 1936-1937 was president of the Federation of State Medical Boards; was a member of the National Board of Medical Examiners of the United States and a member of the executive committee; since 1930, with the exception of 1934, was a member of the House of Delegates of the American Medical Association and chairman of the Section on Preventive and Industrial Medicine and Public Health, 1932-1933; member of the Southern Surgical Association; past president and secretary of the Medical Association of the State of Alabama; fellow of the American College of Surgeons; as a fellow of the American Public Health Association had an active part in its various activities, having served as chairman of the section on public health officers and as a member of the executive committee and governing council of the association; past president of the Southern Branch, American Public Health Association; past president of the Conference of State and Provincial Health Authorities of North America; served as a major in the medical corps of the United States Army during the World War; in 1940 chairman of the National Malaria Committee; state chairman for Alabama of the Committee on Medical Preparedness of the American Medical Association; aged 65; died, November 9, of coronary occlusion.

Joseph Storer Wheelwright * New York; Cornell University Medical College, New York, 1900; associate in physiology from July 1, 1914 to June 30, 1919 and instructor in surgery from July 1, 1919 to June 30, 1920; fellow of the American College of Surgeons; served during the World War; president of the medical board and chief of the staff of the Southampton (N. Y.) Hospital; member of the board of consultants of the Columbia-Presbyterian Medical Center; secretary of the board of the Doctors Hospital; aged 65; died, October 9, of cerebral hemorrhage while at Long Point, 30 miles southwest of Simcoe, Ont.

Ira Alphonso Darling * Torrance, Pa.; University of Vermont College of Medicine, Burlington, 1911; fellow of the American College of Physicians; member of the American Psychiatric Association; superintendent of the Torrance State Hospital; formerly superintendent of the Warren (Pa.) State Hospital and the Springfield State Hospital, Sykesville, Md.; member of the executive committee of the mental hygiene division, Public Charities Association of Pennsylvania; served during the World War; aged 53; died, October 10, of coronary thrombosis.

Ollie Paxton Board * Birmingham, Ala.; Louisville (Ky.) Medical College, 1903; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served during the World War; past president of the Jefferson County Medical Society; visiting surgeon, South Highlands Infirmary and the Hillman Hospital; aged 59; was killed, October 15, near Athens, Ohio, in an automobile accident.

George Fordham * Powellton, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1907; fellow of the American College of Physicians; past president of the Fayette County Medical Society; veteran of the Spanish-American and World wars; formerly on the staff of the Morris Memorial Hospital for Crippled Children, Milton; aged 63; died, October 4, of coronary occlusion.

Arthur Bacon Breese, Syracuse, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1881; professor emeritus of clinical gynecology at the Syracuse University College of Medicine; fellow of the American College of Surgeons; surgeon, Memorial Hospital; consulting surgeon, Onondaga General Hospital; aged 83; died, October 13.

Emil Otto Ficke, Davenport, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; served during the World War; formerly county and city physician; for many years physician for the county insanity commission; aged 61; died, October 7, in the Mercy Hospital following an operation on the gallbladder.

William A. D. Dyke, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C., 1929; first lieutenant in the medical corps of the U. S. Army from Dec. 3, 1932 to Jan. 7, 1935; acting assistant surgeon, United States Public Health Service; formerly a lawyer; aged 49; was killed, September 27, in an automobile accident at Tacoma, Wash.

Herbert D. Gardner, Miami, Fla.; Jefferson Medical College of Philadelphia, 1880; past president and secretary of the Lackawanna County (Pa.) Medical Society; at one time coroner

of Lackawanna County, Pa.; staff surgeon, Scranton Private Hospital, from 1899 to 1925; staff surgeon, Scranton State Hospital, from 1900 to 1910; aged 85; died, October 13.

Walter Speisser Goodale, Buffalo; University of Buffalo School of Medicine, 1903; member of the Medical Society of the State of New York; professor of hygiene and public health emeritus at his alma mater; superintendent of the Edward J. Meyer Memorial Hospital (Buffalo City Hospital); aged 66; died, October 8, of coronary thrombosis.

James Vane Seids * Cleveland; Western Reserve University School of Medicine, Cleveland, 1920; fellow of the American College of Surgeons; senior clinical instructor in surgery at his alma mater; aged 47; on the staffs of the City Hospital and St. Luke's Hospital, where he died, October 11, of amyotrophic lateral sclerosis.

Ernest Page Fuller, Lawrence, Mass.; University and Bellevue Hospital Medical College, New York, 1899; member of the Massachusetts Medical Society; on the staff of the Lawrence General Hospital; aged 68; died, September 14, of carcinoma of the prostate with metastases to the pelvic bones and left femur.

Henry Thomas Sutton, Zanesville, Ohio; Medical College of Ohio, Cincinnati, 1885; member of the Ohio State Medical Association; fellow of the American College of Surgeons; at one time health officer; aged 79; one of the founders of the Good Samaritan Hospital, where he died, October 1, of pernicious anemia.

George R. Sledge, Parksley, Va.; University of Maryland School of Medicine, Baltimore, 1903; member of the Medical Society of Virginia; also a pharmacist; at one time chairman and member of the county school board; aged 61; died, October 3, in the Lenox Hill Hospital, New York, of coronary thrombosis.

Karl Stanley Simpson, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1903; member of the Medical Society of the State of Pennsylvania; veteran of the Spanish-American and World wars; aged 62; on the staff of the Shadyside Hospital, where he died, October 8, of coronary sclerosis.

Isaac N. Hatfield, Bluffton, Ind.; State University of Iowa College of Medicine, Iowa City, 1884; member of the Indiana State Medical Association; past president and secretary of the Wells County Medical Society; aged 85; died, October 13, in the Wells County Hospital of chronic myocarditis.

Curt Benno Hardt * Woodmere, N. Y.; Johann Wolfgang Goethe-Universität Medizinische Fakultät, Frankfurt-am-Main, Prussia, Germany, 1933; formerly clinical assistant in medicine on the staff of the Hospital for Joint Diseases, New York; aged 32; died, October 16, of pneumonia.

Charles Slater, South Ozone Park, N. Y.; University of Glasgow Medical Faculty, Scotland, 1934; member of the Medical Society of the State of New York; member of the Canadian Army Medical Corps; aged 37; was found dead, October 2, in Toronto, Ont., Canada.

George Arnold Holm, Washington, D. C.; University of Minnesota Medical School, Minneapolis, 1915; member of the Medical Society of the District of Columbia; senior medical officer of St. Elizabeth Hospital; aged 53; died suddenly August 25, of coronary thrombosis.

Andrew Gustavus Sandblad, McKeesport, Pa.; Omaha Medical College, 1894; member of the Medical Society of the State of Pennsylvania; aged 75; on the consulting staff of the McKeesport Hospital, where he died, October 5, of cerebral hemorrhage and arteriosclerosis.

John Charles Frey * Syracuse, N. Y.; Syracuse University College of Medicine, 1920; aged 45; on the staff of the Hospital of the Good Shepherd, Syracuse University, where he died, October 8, of acute appendicitis, pyelophlebitis and streptococcal viridans septicemia.

Henry Norris, Bryn Mawr, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; member of the Medical Society of the State of North Carolina; fellow of the American College of Surgeons; served during the World War; aged 66; died, October 6.

Thomas Ap Roger Jones, Knoxville, Tenn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; member of the Tennessee State Medical Association; served during the World War; aged 74; died, October 9, in the Knoxville General Hospital.

Kenneth M. Kelley, Texarkana, Ark.; Memphis (Tenn.) Hospital Medical College, 1899; formerly county health officer, and mayor; for many years on the staff of the Michael Meagher Hospital; aged 81; died, October 5, of uremia, diabetes mellitus and carcinoma of the larynx.

Jesse M. Shackelford, Martinsville, Va.; Baltimore Medical College, 1891; member and formerly vice president of the West Virginia State Medical Association; physician and owner of a hospital bearing his name; aged 71; died, October 2, of cerebral hemorrhage.

George Abell Russell, Boonville, Mo.; Hahnemann Medical College and Hospital, Chicago, 1888; member of the Missouri State Medical Association; formerly county coroner and county and city health officer; aged 80; died, October 2, of pernicious anemia.

Jack Richard McMichael Ⓢ Quitman, Ga.; University of the South Medical Department, Sewanee, Tenn., 1907; chairman of the county board of health; formerly member of the state board of health; aged 57; died, October 6, of coronary thrombosis.

Harry T. Harter, Newtonville, Ind.; Louisville (Ky.) Medical College, 1898; member of the Indiana State Medical Association; aged 72; died, October 16, at St. Joseph's Hospital, Lexington, Ky., of adenocarcinoma of the sigmoid with metastases.

Theodor Adolph Tosch, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; served during the World War; aged 68; died, September 27, in the Deaconess Hospital of cerebral hemorrhage and hypertension.

Albert Edward Sutton, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1909; served during the World War; on the staff of the Toronto East General Hospital; aged 55; died, October 5, of injuries received when struck by a train.

George Thomas McMurray, Farmingdale, N. Y.; Long Island College Hospital, Brooklyn, 1906; at one time on the staffs of the Hospital of the Holy Family and St. Mary's Hospital, Brooklyn; aged 57; died, October 6.

Le Roy Isaac Walker, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1901; aged 63; on the staff of the Women's Homeopathic Hospital, where he died, September 30, of bronchogenic carcinoma.

Robert Ambrose Joyce, Monroe, N. Y.; Bellevue Hospital Medical College, New York, 1873; at one time surgeon for the fire department of the city of New York; aged 90; died, October 16, of cerebral hemorrhage.

Mary Hadley Smith, Long Beach, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; formerly resident physician at the Willard (N. Y.) State Hospital; aged 85; died, October 8.

John Willis Conley Bowman, Brookhaven, Miss.; Mississippi Medical College, Meridian, 1907; aged 63; died, August 13, in the King's Daughters' Hospital of cerebral thrombosis, arteriosclerosis and hypertension.

Thomas J. Stephenson Ⓢ Anderson, Ind.; Illinois Medical College, Chicago, 1898; on the staff of St. John's Hickey Memorial Hospital; aged 73; died, October 5, of cerebral hemorrhage and myocarditis.

Frederick Hugh Goddard Ⓢ Rochester, N. Y.; Western Reserve University Medical Department, Cleveland, 1889; aged 77; died, October 12, in the Highland Hospital of arteriosclerosis and heart disease.

John Voyt Wilson Ⓢ Pittsburgh; University of Pittsburgh School of Medicine, 1913; aged 53; died, October 2, in the Allegheny General Hospital of hypertension, coronary disease and cholelithiasis.

Nathaniel P. Moss, Roanoke, Va.; Medical Department of Tulane University of Louisiana, New Orleans, 1887; for many years bank president and president of the school board; aged 77; died, October 10.

John Roscoe Steagall, Portland, Ore.; Rush Medical College, Chicago, 1912; served during the World War; aged 63; died, September 25, of coronary thrombosis, sclerosis and angina pectoris.

John William Eustace, Buffalo; University of Buffalo School of Medicine, 1930; member of the Medical Society of the State of New York; aged 36; died, October 11, of coronary thrombosis.

Joseph Hardy, St. Louis; Washington University School of Medicine, St. Louis, 1892; member of the Missouri State Medical Association; aged 80; died, October 14, in St. John's Hospital.

James Poesy Wood, Cedar Grove, Ga.; University of the South Medical Department, Sewanee, Tenn., 1901; member of the Medical Association of Georgia; aged 71; died, September 29.

David Franklin Longenecker, San Diego, Calif.; Jefferson Medical College of Philadelphia, 1876; aged 87; died, October 2, of uremia and prostatic hypertrophy with obstruction.

Alonzo Atchison Cotton, Detroit; State University of Iowa College of Homeopathic Medicine, Iowa City, 1886; aged 79; died, October 7, of uremia, acute nephritis and hypertension.

Allston Moore Willcox, Conway, S. C.; Medical College of the State of South Carolina, Charleston, 1913; served during the World War; aged 53; died in October at Manning.

Kenneth George Theis Ⓢ Nyack, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1928; aged 40; died, October 16, of malignant hypertension.

Albert B. Hagerthy, Ashland, Maine; Medical School of Maine, Portland, 1903; member of the Maine Medical Association; for many years coroner; aged 62; died in October.

Edward Dwight Chapman, Daytona Beach, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1876; aged 87; died, September 17, of myocarditis.

Jennie A. Sausser Green, Portland, Texas; Woman's Medical College, Chicago, 1890; aged 83; died, October 4, in Winston-Salem, N. C., of cerebral hemorrhage.

Stanley Gordon Herbert, Winnipeg, Man., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1919; aged 46; died, September 28, of asphyxiation.

Josiah B. Keylor, Cochranville, Pa.; College of Physicians and Surgeons, Baltimore, 1885; bank president; aged 83; died, October 17, in the Coatesville (Pa.) Hospital.

Robert Dellen Harper Ⓢ Loneoak, Ky.; Barnes Medical College, St. Louis, 1902; president of the McCracken County Medical Society; aged 62; died, October 16.

A. J. Odom, Berlin, Ga.; University of Georgia Medical Department, Augusta, 1905; member of the Medical Association of Georgia; aged 64; died, October 6.

Sumner S. Bever, Amazonia, Mo.; Northwestern Medical College, St. Joseph, 1888; formerly county coroner; aged 74; died, October 7, of cerebral hemorrhage.

Maurice Simon Avidan Ⓢ Newark, N. J.; College of Physicians and Surgeons, Baltimore, 1910; served during the World War; aged 53; died, October 17.

William J. Blackburn, Salem, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 79; died, October 5, of carcinoma of the prostate.

A. Frank Lampman, Wilkes-Barre, Pa.; Baltimore Medical College, 1894; aged 68; died, October 10, in the Wilkes-Barre General Hospital of coronary occlusion.

Percival John Abbott, Detroit; Detroit College of Medicine, 1911; aged 58; died, October 7, in the Grace Hospital of intussusception and diffuse peritonitis.

Ora E. Throckmorton, Battle Ground, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1897; aged 74; died, October 4, of paralysis agitans.

Frank George Hope, Sioux City, Iowa; Sioux City College of Medicine, 1906; member of the Iowa State Medical Society; aged 58; died, October 13.

Richard Sawyer Blanchard, Honolulu, Hawaii; Harvard Medical School, Boston, 1940; intern at the Queen's Hospital; aged 28; died, September 27.

Sallie Jones Jagers, Washington, D. C.; Eclectic Medical College of the City of New York, 1887; aged 92; died, October 26, of arteriosclerosis.

Samuel G. Kennedy, Tulsa, Okla.; Kansas City (Mo.) Medical College, 1898; aged 76; died, September 27, of endocarcinoma of the prostate.

James Dean MacDonald, Huntsville, Ont., Canada; Western University Faculty of Medicine, London, 1907; aged 66; died, October 5.

Jacob DeVries, Grand Rapids, Mich.; Physio-Medical College of Indiana, Indianapolis, 1890; aged 77; died, October 7, of mitral regurgitation.

Eckley G. Sharp, Guthrie, Okla.; Eclectic Medical Institute, Cincinnati, 1893; aged 75; died, September 6, of cerebral hemorrhage.

Arsine Arthur Lefebvre, Montreal, Que., Canada; University of Montreal Faculty of Medicine, 1924; aged 43; died, September 4.

James Alexander Phillips, Brantford, Ont., Canada; Trinity Medical College, Toronto, 1887; aged 75; died, September 4.

Rozell Berryman, Baltimore; Baltimore Medical College, 1893; aged 80; died, October 1, of carcinoma of the stomach.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Activanad.—Charles J. Ahsbahr, trading as Neo-Products Company of America, New York, promised the Federal Trade Commission in December 1940 to discontinue certain misrepresentations in the sale of this product. Among them were that the thing is praised or recommended by eminent physicians or psychiatrists; that it strengthens the body or benefits persons afflicted with fear, anxiety, irritability, worry or fatigue; that it prevents chronic disorders or has any therapeutic value in the prevention of any ailment or disease; that it builds up the body, promotes formation of new blood, strengthens the muscles, promotes sleep, acts as an effective aphrodisiac, or does some other things. In the same month Lester Meyers, New York, who conducts an agency which handles the "Activanad" advertising, also promised the Commission that he would discontinue these misrepresentations.

Beauty Builder and Beauty Fount.—These are vapor-electric bath cabinets put out by the Gellman Manufacturing Company, Rock Island, Ill. In December 1940 the concern signed a stipulation with the Federal Trade Commission promising to cease representing that these cabinets have a direct value in permanent reduction of weight; that by means of vapor heat or infra-red or ultraviolet rays these devices help eliminate excess fat, that they rid the body of harmful toxins or "cure" or "banish" or "crase" fatigue or benefit nervous or underweight persons.

Darmela Products.—These include "Darmela Salve" and "Darmela Liquid" and are put out by Joseph H. Miller, trading as Darmela Laboratory, Chicago. In November 1940 the Federal Trade Commission reported that it had got him to agree to cease representing that either of his products is a competent treatment or effective remedy for open or running wounds or sores (cutaneous ulcers) unless it is explained in direct connection therewith that they will have no effect on the condition when it is due to varicose veins, tuberculosis or syphilis; that either is a competent treatment for shingles, except possibly for relief of the pain and itching; that Darmela Liquid is a competent treatment for stiffness, numbness, paralytic stress and some other conditions, except as it may give temporary relief from pain or discomfort associated with those conditions. Miller also promised to cease representing that the liquid is effective for coughs or colds or that he owns, controls or operates a laboratory.

Digesto-Pep and Coldlax.—Smith Brothers Drug Company of Greensboro, N. C., signed a stipulation with the Federal Trade Commission in December 1940 promising to discontinue certain misrepresentations in the sale of these two products. Among them were that "Digesto-Pep" is a remedy for stomach disorders or will do more than temporarily relieve stomach discomforts associated with gastric hyperacidity, or enable a person to eat whatever he wishes without discomfort; or that "Coldlax" will attack a cold at the seat of the trouble or do anything more than temporarily relieve its symptoms.

Entromul.—This was represented in the advertising to be valuable in the treatment of various stomach and intestinal disturbances, particularly those due to excess acid, putrefactive germs in the intestine or simple mucous colitis. In December 1940 Thomas J. McBride, trading as the Entromul Company of Los Angeles, promised the Federal Trade Commission that he would discontinue these misrepresentations. The stipulation that he signed was supplemental to one accepted by the Commission in February 1937, the terms of which were still in effect. Following up his stipulation in December 1940, the N. J. Newman Advertising Agency of Los Angeles signed a similar one, promising to discontinue the misrepresentations mentioned.

F. K. Invisible Nasal Filter.—This was represented by the F. Koehler Manufacturing Company, Inc., of Newport, Ky., as competent to relieve the discomforts of hay fever, rose fever, sinus infections and asthma, protect the nasal passages from pollen and give effective relief for headaches caused by gasoline fumes or for coughing or a phlegm-filled throat condition caused by asthma or sinus infection. In November 1940 the Koehler concern promised the Federal Trade Commission that it would discontinue these misrepresentations.

House of Westmore Cosmetics.—These are put out by a Ferce H. Westmore and the House of Westmore, Inc., Burbank, Calif. In November 1940 this person promised the Federal Trade Commission that he would cease representing that cosmetics in general contain undesirable or unflattering colors which may give a harsh or aged appearance, whereas the House of Westmore cosmetics have had the color filtered out of them.

Nix Deodorant Cream.—This was put out by one P. Edwards, trading as the Nix Cosmetics Company, Memphis, Tenn. In December 1940 he signed a stipulation with the Federal Trade Commission to cease representing that his cream stops the flow of perspiration or its odor for days; that it affects these conditions in a new way or neutralizes or has any other substantial effect on perspiration acids. In January 1941 Cole and Company of Memphis, which handles the Nix advertising, signed a similar stipulation with the Commission.

Ofria.—This product, also known as L'Unguento Ofria, Ofria Pile Remedy and Ofria Ointment, was put out by one Maria Ofria of Brooklyn, trading under the name of Philip Ofria. In November 1940 the Federal Trade Commission reported that it had got her to sign a stipulation promising to cease representing that her product will cure or dry up hemorrhoids, pruritus and similar troubles or that it will afford lasting relief. She also agreed to cease using the word "remedy" in the trade name of this product or any other mixture of similar composition.

Peano-Oil.—This was put out by six co-partners who traded as the Peanut Products Company, Tuskegee, Ala. In November 1940 the Federal Trade Commission reported that it had got these persons to agree to cease representing that the use of their product will result in healthy hair, will restore the natural oil of the hair, will prevent hair from falling out or becoming brittle or prevent baldness; or that it nourishes the scalp or that it is the discovery of an eminent scientist.

Pilot Health Course.—This was exploited by a Charles B. McFerrin, Orlando, Fla., who also published the *Spot Light Magazine*. McFerrin for years has represented himself as a "diet specialist." In November 1940 the Federal Trade Commission got him to sign a stipulation agreeing to cease from representing that his magazine contains information of any value whatever for any disease or affliction, including gallbladder trouble, liver disorders, rheumatism, anemia and other ailments; or that "The Pilot Health Course" offers any conceivable benefit to sinus trouble, bronchitis, asthma and some twenty-five other disorders, or enables one to have health, prosperity or happiness.

Pow-A-Tan Herb Tonic.—The Pow-A-Tan Medicine Company, Huntington, W. Va., put this out under the misrepresentations that it was a cure or remedy or competent treatment for all common ailments, such as rheumatism, neuritis, arthritis, indigestion, hemorrhoids, la grippe, lumbago and similar complaints. In November 1940 the concern stipulated with the Federal Trade Commission that it would discontinue these misrepresentations and a few others.

Q-Loid.—The Magay Corporation of New York, in January 1941, stipulated with the Federal Trade Commission that it would cease representing that "Q-Loid" would accomplish results similar to those obtained by injections of colloidal sulfur or that it was an effective remedy for arthritis beyond furnishing temporary symptomatic relief in some forms of arthritis when there is a sulfur deficiency. In 1938 government chemists reported that Q-Loid consisted of white tablets and yellow ones, the first containing 5 grains (0.3 Gm.) of acetylsalicylic acid per tablet and the second, sulfur (from 0.2 to 0.4 grain [0.013 to 0.026 Gm.]) and antipyrine (0.2 to 0.3 grain [0.04 Gm.]) per tablet. At that time the government declared that Q-Loid was fraudulently represented as a remedy for arthritis, rheumatism and allied conditions.

Ramstead Treatment.—The Ramstead Company, Inc., Milwaukee, having promoted this product as a competent treatment for stomach ailments generally, whose use would enable a person to tolerate all kinds and types of foods and would act as a substitute for surgical treatment of gastric ulcers, signed a stipulation with the Federal Trade Commission in November 1940 promising to discontinue these and other misrepresentations. The stipulation was supplementary to one that the same company had made with the Commission in February 1932.

Rose Laird Cosmetics.—These were put out by a Rose Helen Kingstone, trading as R. H. Laird Company and Rose Laird, New York, who in December 1940 promised the Federal Trade Commission to discontinue certain misrepresentations in her advertising. Among these were that "Rose Laird's Greaseless Lubricant, Protective Face Lotion, Overnight Cream, and Liquid Facial Soap" alone or in combination would correct blemishes or other cutaneous ills or enable one to acquire or retain a clear skin; or that by use of the product one would not have a bumpy skin, excess oil, eruptions, coarse pores or blackheads. In January 1941 similar promises were made to the Commission by AW-Advertising, Inc., of New York.

Stuart's Tablets.—Apparently this is the product that used to be sold as "Stuart's Dyspepsia Tablets." In December 1940 the F. A. Stuart Company, Marshall, Mich., and Benson & Dall, Inc., Chicago, an advertising agency, promised the Federal Trade Commission to cease representing that these tablets are a remedy for any dysfunction of the stomach, or more efficacious as an antacid than any similar preparations, have any other action on the stomach than temporary relief of acidity or prevent the occurrence of any dysfunction of the stomach.

Vapo-Cresolene.—In November 1940 the Federal Trade Commission announced that it had got the Vapo-Cresolene Company, Chatham, N. J., to sign a stipulation to discontinue certain misrepresentations in its advertising of this product. Among these were that Vapo-Cresolene is a competent treatment for colds or a remedy for spasmodic or ordinary croup, whooping cough, "children's diseases," pneumonia, influenza or deep chest colds.

Wonder Glo.—Werner Walter, trading as Wonder Products Company, Canton, Ohio, promised the Federal Trade Commission in August 1940 that he would discontinue representing that this alleged cleaner and water softener, put out also as a shampoo, has any particular value when used as a shampoo aside from its power to soften hard water.

Correspondence

HYPERSENSITIVITY TO SULFATHIAZOLE

To the Editor:—In THE JOURNAL, October 18, page 1378, under correspondence, Dr. Merritt H. Stiles calls attention to what he considers an omission in the table appearing in the article by Dr. E. P. Lieberthal and me (Pemphigus Follicular-like Eruption Following Use of Sulfanilamide and Sulfapyridine, THE JOURNAL, September 6, p. 850). This table, which was presented by Dr. Perrin Long as a summary of the clinical toxic manifestations of sulfanilamide, sulfapyridine and sulfathiazole was, in my estimation, a superlative tabulation of information up to the time the table was presented by Dr. Long before the Pan American Scientific Congress on May 15, 1940. The status of sulfanilamide, its related drugs and their toxic manifestations is still in a state of flux, as revealed by the great number of contributions to the literature listed in recent editions of the *Quarterly Cumulative Index* dealing with the various phases of the clinical application of these drugs and their toxic sequelae. In the table it is stated that nausea and vomiting following sulfathiazole is rare, and it is my feeling that Dr. Stiles's communication referring to his article in the *Pennsylvania Medical Journal* is simply further corroboration of this statement in Dr. Long's table.

MAX S. WIEN, M.D., Chicago.

MARRIAGE IN EPILEPSY

To the Editor:—I realize that answers to the questions propounded in Queries and Minor Notes must be brief, but a half answer may be worse than none. This is the case in the answer to "Marriage in Epilepsy" on page 1402 of the issue of October 18. Largely on the basis of the electroencephalographic evidence which my associates and I have gathered, the writer states that the only hope of eliminating epilepsy is by birth control among epileptic adults. He overlooks the fact that the brain wave studies indicate that for every epileptic patient there are probably twenty or more nonepileptic patients who nevertheless are carriers of this or an allied disorder. Therefore, childlessness of all persons with epilepsy would eliminate only 5 per cent of epilepsy. Prohibitions applied to a person with epilepsy apply with equal force to one half of his relatives and to something like 10 per cent of the whole population. Again, the probability of having affected progeny depends in part on whether the person whom the epileptic person marries carries a predisposition to epilepsy. The marriage of two normal carriers of this disorder is more dangerous than the marriage of an epileptic person to a noncarrier. Logically brain wave tracings of both partners to a marriage should be secured if the physician is to offer specific advice to an individual. Even so he should consider the possibility suggested by unpublished observations that unusual, so-called "abnormal" frequency of waves may be associated with high attainment or genius. Many implications of electroencephalography are as yet unexplored.

This technic is not yet available for most epileptic persons who may wish to marry. However, the degree of inheritance of epilepsy is greater in some individuals than in others, and there is certain statistical evidence which makes the outlook relatively favorable for the patient whose history is given: her family history is unmarred, her mentality is normal, and seizures began relatively late in life. Furthermore, her other physical and mental characteristics, which presumably are also transmittable, are socially desirable. If she will select a mate whose family and personal history are as clear as her own, there is less than one chance in twenty that one of her two children, if she has but two, will have epilepsy. Whether she wishes to

take this chance is something she, and not her doctor, will need to decide.

The correspondent asked for references. The latest summing up of evidence will be found in the article on the inheritance of cerebral dysrhythmia and epilepsy in the *Archives of Neurology and Psychiatry* 44:1155 (Dec.) 1940 and in Erickson, Theodore, and Penfield, Wilder: *Epilepsy and Cerebral Localization*, Springfield, Ill., Charles C. Thomas, 1941, and in Lennox, W. G.: *New Light on Epilepsy and Migraine*, New York, Harper Brothers, 1941.

Incidentally, the correspondent is giving too small a dose of phenobarbital and there would seem to be no indication for the use of hormones.

WILLIAM G. LENNOX, M.D., Boston.

MERCUPURIN

To the Editor:—During the past six years each of us has administered a large number of doses of mercupurin to patients with congestive heart failure without any serious toxic reactions. Therefore we were startled on learning that we had independently within the last two months observed three deaths following an intravenous injection of the drug. On further inquiry we found that others of our acquaintance had recently observed extremely serious and even fatal reactions following promptly after the injection of mercupurin. Since the technic had been the same as that used by us in giving several thousand injections of mercupurin, we are at a loss for an adequate explanation of these recent reactions. Tyson (THE JOURNAL, September 20, p. 998) reported dangerous reactions after the injection of mercurials in cases of nephrosis; none of the fatal or nonfatal reactions noted by us occurred in patients with this malady.

Since no postmortem examination was made, we will not attempt to give complete reports of the cases. Briefly, the patients all suffered from congestive heart failure, one of syphilitic, another of hypertensive and the last of arteriosclerotic origin. All had received mercupurin previously. The last dose in each case was 2 cc. The drug was given slowly by vein. Death in each case was immediate.

If more such deaths have been occurring recently it would be well to have the subject of mercurials reexamined. It is for this reason that we are bringing our experiences to your attention at this time. We suggest that until further investigation mercupurin be given intramuscularly. The diuresis following intramuscular injection is usually satisfactory.

BILATERAL THROMBOSIS OF ANTERIOR CEREBRAL ARTERY

To the Editor:—In THE JOURNAL, September 27, Judah Marmor and M. R. Sapirstein reported a case of "Bilateral Thrombosis of Anterior Cerebral Artery Following Stimulation of a Hyperactive Carotid Sinus."

The authors gave the blood count of this patient as hemoglobin 114 per cent, red cells 6,100,000 and leukocytes 14,000 with a normal differential. The hematocrit test, however, was within normal limits.

They conclude that "the slowing of the pulse and the fall in blood pressure produced by stimulation of the carotid sinus was a contributory factor in prematurely precipitating the cerebral thrombosis . . . in elderly persons with evidence of advanced arteriosclerosis, cerebral as well as myocardial. It may well be that carotid sinus stimulation is not entirely without danger in such persons."

While their conclusion is logical, I think that they should also have stressed the probability of the polycythemia, although not vera, having been a predisposing factor for the thrombosis in this case. It would seem advisable then that in elderly patients with polycythemia stimulation of the carotid sinus should be performed with caution.

L. FELDMAN, M.D., Chicago.

NOTE.—This letter was referred to the authors, who reply:

To the Editor:—In the writing of our report Dr. Sapirstein and I had seriously weighed the question of whether or not the polycythemia had been a significant predisposing factor for the thrombosis and after thorough consideration had come to the conclusion that it had not. Our opinion was based chiefly on the fact that the hematocrit test was within normal limits, which is not the case in true polycythemia. This seemed to indicate that we were dealing merely with a high normal blood count of no particular pathogenic significance, and we concluded, therefore, that the advanced cerebral arteriosclerosis was the important predisposing factor in our case.

Nevertheless, we would agree that the statement expressed by your correspondent is a valid one, namely that "in elderly persons with polycythemia, carotid sinus stimulation should be performed with caution." We would carry the concept even further, however, and state that in any person in whom there is a predisposition to thrombus formation, for whatever reason, carotid sinus stimulation should be performed with caution.

JUDAH MARMOR, M.D., New York.

OXYGEN TENT THERAPY IN THE TREATMENT OF ECLAMPSIA

To the Editor:—Under the title "Oxygen Tent Therapy in the Treatment of Eclampsia" Dr. Roy E. Nicodemus published his impression that continuous oxygen therapy, combined with the Stroganoff treatment, played a major part in the recovery of a number of his patients with eclampsia. He states that in a careful perusal of the literature on the treatment of eclampsia he could find no reference to the use of oxygen other than the early writings of Stroganoff and De Lee on oxygen inhalations instituted immediately after convulsive seizures (THE JOURNAL, October 11, p. 1238). This rediscovery of oxygen as an important adjunct in the treatment of eclampsia is fascinating. A good thing bears repeating. In 1912 investigation concerning certain chemical aspects of autolysis of the liver revealed that the administration of oxygen significantly retarded this phenomenon. It was this observation that served as an impetus to incorporate oxygen administration as a routine in the treatment of eclampsia and severe preeclampsia in which acute degeneration of the liver so frequently occurs (Hofbauer, J. I.: *Jahresk. f. ärztl. Fortbild.* 7:22, 1912). By the same token the administration of chloroform to eclamptic patients, because of its hepatotoxic effect, was strongly deprecated. This view was further elaborated in an address entitled "Recent Advances in the Treatment of Eclampsia Gravidarum." In a survey of certain concrete conditions concerning anoxemia incident to the disorder, it was emphasized that "inhibition of the oxidative processes in eclamptics affords a biochemical basis for the institution of a liberal administration of oxygen to such patients, as recommended by us years ago" (*Am. J. Obst. & Gynec.* 26:311 [Sept.] 1933).

For the rational treatment of preeclampsia and eclampsia a full understanding of the causation and nature of the disorder is the prime prerequisite. Conquest of the etiology of eclampsia has for decades been regarded the supreme task and achievement in obstetrics. Today it is acknowledged that heretofore the magnificent efforts to unravel the problem have resulted in

confessed futility. Recent unavailing attempts to revive the long discredited theory of anaphylaxis or the "pressure theory" signify the present chaotic state of reasoning and confusion as to the pathogenesis and etiology of the toxemia of pregnancy. The jungle of theories will not be cleared until the fundamental facts are mastered.

Using facts, not theories, a forthcoming paper (*West. J. Surg., Gynec. & Obst.*, November 1941) makes an outright bid for arrival at the threshold of certain fundamentals of the etiology of preeclampsia. In accord with Irving, Soma Weiss and others who placed stress on functional disturbances of the arterioles and capillaries as probably holding the key to much of the mystery, the signs and symptoms of "this vascular syndrome of pregnancy" (Weiss) as well as the multiple bodily changes occurring in the disorder are there interpreted in terms of deranged vascular physiology, which pivots on the interaction of three pharmacologically well defined principles—histamine, pitressin, acetylcholine—during gestation. While pitressin and acetylcholine are normal constituents of pregnancy, the first named occurs only in toxemia. This study serves to bring to a realization and conclusion, for the time being, previous investigations quoted in the text. Deviation from current thought is particularly apparent in my consideration of biologic placental insufficiency—reflected anatomically in the well known occurrence of multiple infarcts, hemorrhage and areas of autolysis in the toxemic placenta which reduce its ability to store acetylcholine, estrin and progesterone—as a determining etiologic factor in preeclampsia. This is at sharp variance with the view generally held that certain hitherto undefined products of placental decomposition constitute a basic essential in the pathogenesis of the late toxemia. The attempted coordination, in my paper, of the facts presented is too challenging to be passed over. If examined dispassionately and graciously received, the basic arguments advanced may serve to waive the doctrine that the etiology of the toxemia of pregnancy is utterly obscure. "Let there be light."

J. I. HOFBAUER, M.D., Cincinnati.

NUTRITION

To the Editor:—Dr. Philip R. Trommer (THE JOURNAL, October 11, p. 1283) will do well to check some of his own premises before impugning the opinion of Dr. Logan Clendening with whose timely comment as to the factual dearth of clinical hypovitaminoses I heartily agree. In the dermatologic section of the outpatient clinic from which Dr. Clendening's patients also were drawn, I see extremely little evidence of pellagra, although a dermatologic eye at least intends to be acute to such symptoms. A diet of "6 to 8 cups of coffee a day together with 2 to 3 packs of cigarets" is, incidentally, quite a reliable symptom of hypothyroidism, which is more likely to be the basic cause of "anorexia and loss of weight" than the patient's selection of ingesta. Hypothyroidism is also a cause, frequently enough, of malmetabolism of vitamins, especially of vitamin A. Perhaps with a normal complement of thyroxin some persons would not stay on relief.

RICHARD L. SUTTON JR., M.D., Kansas City, Mo.

RAT BITE FEVER

To the Editor:—In perusing THE JOURNAL of May 24, page 2393, I saw the report of Dr. John Greenwood and Dr. Edmond R. Hess of rat bite fever in an infant aged 11 days. I was once awakened from my sleep within three hours after an infant was born by its crying; I saw a rat biting the child's toe. Following this rat bite the child had rat bite fever.

G. A. BYERS, M.D., North Bend, Neb.

Rhode Island October Report

The Rhode Island Board of Examiners in Medicine reports the written examination for medical licensure held at Providence, Oct. 2-3, 1941. The examination covered 9 subjects and included 82 questions. An average of 80 per cent was required to pass. Three candidates were examined, all of whom passed. Three physicians were licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Loyola University School of Medicine.....	(1933)		1
Tufts College Medical School.....	(1940)		1
Jefferson Medical College of Philadelphia.....	(1939)		1
School	LICENSED BY ENDORSEMENT	Year Grad.	
Boston University School of Medicine.....	(1936)		
Harvard Medical School.....	(1938)		
Tufts College Medical School.....	(1939)		

Kansas September Report

The Kansas State Board of Medical Registration and Examination reports the written examination for medical licensure held at Kansas City, Sept. 23-24, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fourteen candidates were examined, all of whom passed. Nine physicians were licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
University of Kansas School of Medicine.....	(1941, 12)		12
St. Louis University School of Medicine.....	(1940)		1
University of Tennessee College of Medicine.....	(1941)		1
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1922)		Illinois
University of Louisville School of Medicine.....	(1931), (1940)		Kentucky
Tulane University of Louisiana School of Medicine.....	(1935)		Louisiana
University of Michigan Medical School.....	(1935)		Michigan
Creighton University School of Medicine.....	(1939)		California
University of Cincinnati College of Medicine.....	(1940)		Ohio
University of Tennessee College of Medicine.....	(1927)		Tennessee
McGill University Faculty of Medicine.....	(1933)		California

Tennessee June Report

The Tennessee State Board of Medical Examiners reports the written examination for medical licensure held at Knoxville, Memphis and Nashville, June 16-17, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and thirty-eight candidates were examined, 137 of whom passed and 1 failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
George Washington University School of Medicine.....	(1939)		1
Howard University College of Medicine.....			2
Jefferson Medical College of Philadelphia.....			1
University of Pennsylvania School of Medicine.....			1
Meharry Medical College.....	(1940), (1941, 47)		48
Univ. of Tennessee College of Medicine.....	(1940, 2), (1941, 30)		32
Vanderbilt University School of Medicine.....	(1941, 52)		52
School	FAILED	Year Grad.	
University of Tennessee College of Medicine.....	(1941)		

Eighteen physicians were licensed to practice medicine by endorsement from June 5 through August 21. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Alabama School of Medicine.....			Arkansas
College of Physicians and Surgeons.....			B. M. Ex.
University of Chicago.....			Georgia
Johns Hopkins University School of Medicine.....	(1934)		Maryland
University of Michigan Medical School.....	(1936)		Michigan
Wayne University College of Medicine.....	(1940)		Michigan
Washington University School of Medicine.....	(1939)		Missouri
New York Medical College, Flower and Fifth Avenue Hospitals.....	(1939)		N.B. M. Ex.
Duke University School of Medicine.....			N. B. M. Ex.
Western Reserve University.....			Ohio
University of Oklahoma School of Medicine.....			Oklahoma
Jefferson Medical College of Philadelphia.....	(1924)		S. Carolina,
(1938) Pennsylvania.....			Indiana
University of Pennsylvania School of Medicine.....	(1900)		
(1938) New York.....			
Medical College of the State of South Carolina.....	(1939)		S. Carolina
University of Tennessee College of Medicine.....	(1931)		W. Virginia
Medical College of Virginia.....	(1903)		Virginia

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: "Conceded Eminence and Authority" in the Profession as Basis for Licensure Without Examination.—Marburg was licensed to practice medicine in Austria in 1899 and practiced there until 1938, becoming, in the words of some American physicians who certified as to his eminence when he sought a license to practice in New York, "the leading neuropathologist in Europe." In 1938 he immigrated to the United States and subsequently filed a declaration of intention to become a citizen. He was appointed clinical professor of neurology at Columbia University College of Physicians and Surgeons and research neuropathologist at Montefiore Hospital, New York City. He sought a license to practice medicine in New York State without examination by virtue of section 1259 of the Education Law, which authorizes the commissioner of education in his discretion on the approval of the board of regents, in effect, to license without examination a physician licensed by another state, or country, provided the applicant possesses the preliminary and professional qualifications required of an applicant for licensure after examination, has been in reputable practice for ten years or more and has reached a position of conceded eminence and authority in his profession. The commissioner and the board of regents denied the application and Marburg instituted a proceeding to require the approval of his application. The trial court entered such an order and the order was affirmed on appeal by the supreme court, appellate division, third department, New York. (*Marburg v. Cole*, 23 N. Y. S. [2d] 501). The commissioner and the board then appealed to the Court of Appeals of New York.

The sole question presented for the determination of the Court of Appeals was whether or not the refusal to grant Marburg's application was so arbitrary, capricious or unreasonable as to constitute an abuse of the discretion conferred on the commissioner and the board by section 1259 of the Education Law, referred to. That statute, said the Court of Appeals, expressly invests the commissioner of education and the board of regents with a wide discretion, the due exercise of which the courts do not have the power to disturb. Nor do the courts have the power to substitute their judgment for the judgment of the properly delegated administrative officials. Thus in the absence of clear and convincing proof that the discretion has been exercised arbitrarily, unfairly or capriciously, the courts will not interfere. The commissioner and the board have exercised with great caution the broad discretion conferred on them by section 1259 to license eminent men, licensing only four persons under this section since it was enacted in 1918. Each person so singularly honored had attained prior to such licensure a position of eminence and authority in the medical profession. One of the physicians so honored had discovered the Schick test for determining susceptibility to diphtheria. Another physician had been the recipient in 1934 of the Nobel prize in medicine and was the co-discoverer of the cause and cure for pernicious anemia. Another physician had been the originator of the so-called insulin shock treatment for dementia precox or schizophrenia. The fourth physician so licensed had previously been a full professor of gynecology and obstetrics at the University of Toronto Faculty of Medicine and had been called to a full professorship of gynecology and obstetrics by the Columbia University College of Physicians and Surgeons and to the directorship of the Sloane Hospital for Women. Apparently, the board in exercising its broad discretion in determining what constituted "a position of conceded eminence and authority" in the profession had adopted a rigid objective test that the eminence required by the statute is obtained only by an outstanding original contribution in some one field of medicine. They departed from this objective standard in permitting the licensure of the last physician referred to, but in view of his appointments the board concluded that they could, within their discretion, make such an exception since they were satisfied that that physician ranked among the few outstanding men in his profession as evidenced by universal recognition and outstanding appointments in New York State. In the case at

bar, said the Court of Appeals, after full hearings the commissioner and the board have come to the determination that the eminence of Dr. Marburg does not satisfy the standard required by the statute as it has been interpreted by them in the past. It is this determination that the Court is asked to declare to be arbitrary, unfair and capricious, but the Court does not believe that such is the case. It is not claimed by Marburg, nor does the record show, that he is responsible for any outstanding original contribution to any field of medicine. Thus if the eminence of Marburg is in any way to satisfy the high degree of eminence which has been set as the prerequisite for the indorsement of a medical license under this section it must be shown that his eminence in the field of neurology is so great that it can be said to be arbitrary, unfair or capricious for the commissioner and the board to have refused to make an exception to the general standard in his case. While the evidence with respect to Marburg's reputation and his accomplishments is impressive, it did not, in the opinion of the Court, require the board and the commissioner to make an exception to their general standard in Marburg's case nor as a matter of law render their refusal to do so arbitrary, unfair or capricious.

Marburg did not allege, nor was there any evidence to support a claim, that the standard which had been adopted by the commissioner and by the board with respect to license by virtue of section 1259 was arbitrary or unreasonable. The law, said the Court, is well settled that it is not always necessary that license legislation prescribe a specific rule of action. Where it is difficult or impracticable for the legislature to lay down a definite, comprehensive rule, a reasonable amount of discretion may be delegated to the administrative officials. Where the administrative agency has adopted a standard as an interpretation of the broad powers granted to it by the statute, the Court may declare such a standard invalid only in the event that it is so lacking in reason for its promulgation that it is essentially arbitrary. In concluding that the interpretation adopted by the commissioner and the board of the powers confided to them by the legislature through the provisions of the section in question is not unreasonable, the Court adverted to the liberality accorded by New York State to practitioners of other states who have been licensed in the past by virtue of other sections of the medical practice act. The Court quoted figures as to the number of such applicants who have been granted licenses in New York, from which it appeared that of the 1,054 graduates of foreign medical schools admitted to practice medicine in New York after examination in 1939 and 1940, the vast majority were persons who were born in foreign countries and came to this country during the last several years. Thus in the case at bar, where the board of regents has interpreted the words "conceded eminence and authority in his profession" to mean an outstanding original contribution to a certain field of medicine or standing among the first few men of his profession, as evidenced by universal recognition and outstanding appointments to positions of high responsibility in the state, such interpretation cannot be said as a matter of law to be unreasonable or arbitrary.

Since success in this proceeding required the petitioner to establish a clear legal right to the remedy he chose and since it appeared that the power granted to the commissioner and to the board under section 1259 is more a power to confer a privilege and does not create an absolute right in an applicant, no order to compel the exercise of the power will lie except where the refusal is arbitrary, unfair or capricious. There being no evidence to sustain such a finding, the Court reversed the action of the court below requiring the issuance of a license to Marburg.—*Marburg v. Cole*, 36 N. E. (2d) 113 (N. Y., 1941).

Optometry Practice Acts: Illegality of Activities of Licensed Physician Employed by Jewelry Store to Practice Optometry.—Gilmore, who was licensed to practice neither medicine nor optometry, operated a jewelry store and in connection therewith maintained an optical department in which refraction was done by Sidel, apparently a licensed optometrist, and by Bertrem, a licensed physician, both of whom were employed by Gilmore on a straight salary basis. The Florida State Board of Optometry instituted proceedings to enjoin Gilmore, Sidel and Bertrem from practicing optometry. The trial court restrained Gilmore from continuing to employ Sidel for the practice of optometry but refused to restrain

Gilmore himself from practicing or from continuing to employ Bertrem, the licensed physician, to practice. The board then appealed to the Supreme Court of Florida.

Section 11 of the Florida optometry practice act (Laws of Florida, Acts of 1939, chapter 19031) makes it "unlawful for any corporation, lay body, organization, group, or lay individual to engage, or undertake to engage in, the practice of Optometry through means of engaging the services, upon a salary, commission, or lease basis, or by other means or inducement, any person licensed to practice Optometry in the State of Florida." Section 8 of this same act makes it unlawful for any person to practice optometry in the state without first procuring a certificate of registration and license but provides that "the terms and provisions of this Act shall not apply to duly licensed physicians and surgeons." The jeweler and the physician on appeal argued that the action of the trial court was proper because, while section 11 expressly prohibits an unlicensed person from practicing optometry through a person licensed to practice optometry, section 8 frees all physicians from the restrictions imposed generally on those who are privileged to represent themselves as optometrists. The Supreme Court, however, would not so construe the act. The provision, said the Court, that the act should not apply to duly licensed physicians and surgeons is included in the section making it unlawful to practice without registration and license. It is patent that physicians are exempt from the provisions of the optometry practice act because their training is so thorough that they are fitted to perform those services for which optometrists are also qualified. Thus, a physician, as such, is not required to procure a certificate of registration and license as a registered optometrist to practice optometry lawfully. If a physician practices optometry on his own account and responsibility he is by schooling presumed properly equipped and there is no need to examine into his fitness, the diagnoses and prescriptions for correction and relief of the human eye being an incident to and included in his medical education. But when a physician steps out of character and becomes the employee of a person himself not entitled to engage in the practice of optometry a direct violation of section 11, quoted above, results. The provision of the act of which the jeweler has run afoul denounces the employment on a salary basis of "any person licensed to practice Optometry." Here qualifications are not the criterion but the act condemned by the legislature is the hiring by one unlearned in the profession of another who is permitted by his knowledge to engage in it. The evil sought to be prevented by such a relationship may be tersely stated. In this situation the responsibility of the employee in the performance of services important to those whose eyes are abnormal is confused with his loyalty to the employer, while the latter, although unskilled in the work, is accountable to patients to whom he is not personally permitted to minister. The result is a broken relationship between a professional man and those who engage his services.

The court concluded, therefore, that the optometry practice act prohibits the practice of optometry under the circumstances here present and accordingly reversed the decree of the trial court refusing to enjoin Gilmore and Bertrem, the licensed physician, from engaging in the practice of optometry.—*State Board of Optometry v. Gilmore*, 3 So. (2d) 708 (Fla., 1941).

COMING MEETINGS

- American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Diveley, 1103 Grand Ave., Kansas City, Mo., Secretary.
- National Society for the Prevention of Blindness, New York, Dec. 4-6. Mrs. Eleanor Brown Merrill, 1790 Broadway, New York, Executive Director.
- Puerto Rico, Medical Association of, Santurce, Dec. 11-14. Dr. David E. García, P. O. Box 3866, Santurce, Secretary.
- Radiological Society of North America, San Francisco, Dec. 1-5. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Society for the Study of Asthma and Allied Conditions, New York, Dec. 6. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Society of American Bacteriologists, Baltimore, Dec. 29-31. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Southern Surgical Association, Pinchurst, N. C., Dec. 9-11. Dr. E. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Surgical Association, St. Paul, Dec. 5-6. Dr. Arthur R. Metz, 2449 Washington Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Erythroblastosis and Transfusion Accidents.—Burnham calls attention to the common etiology of two apparently unrelated conditions, erythroblastosis fetalis and certain transfusion accidents occurring in pregnancy. The etiology of erythroblastosis fetalis resides in an immunologic incompatibility between the fetus and the mother, that is, there is present in the fetal erythrocytes an antigen inherited from the father which is lacking in the mother. The antigen diffuses from the child into the mother's circulation and stimulates the formation of destructive antibodies. These antibodies readily diffuse into the fetal circulation, where they can attack the erythrocytes which contain the antigen and thereby cause erythroblastosis. Should such a mother be given a transfusion containing the antigen, the destructive antibodies (agglutinins) in her circulation would agglutinate and hemolyze the transfused blood causing the frequently fatal oliguria or anuria. These reactions occur between bloods of the same group and in spite of apparently compatible cross matching. Stated in another way, when a rhesus monkey antigen negative woman is carrying an Rh (rhesus) positive baby, sometimes the baby's blood stimulates the mother to form the anti-Rh agglutinin. This antibody, in turn, passes back through the placenta and destroys the baby's Rh positive blood and causes erythroblastosis. Should the mother be transfused with Rh positive blood, the agglutinin can agglutinate and destroy the transfused blood and its hemoglobin blocks the kidneys and causes oliguria or anuria. Should a mother of a possible erythroblastosis baby require a transfusion, it is safer to determine her Rh status and to use a corresponding donor, usually an Rh negative donor. Should no precautionary measures be available in suspicious cases it is safer to use blood

substitutes, preferably blood plasma. The erythroblastosis group must be broadened to include not only hydrops fetalis, icterus gravis and congenital anemia but some of the macerated fetuses not due to syphilis, diabetes or toxemia and also many, if not most, of the anemias of the newborn. Some cases of miscarriage may likewise belong in this group.

Prothrombin Concentration and Liquid Petrolatum.—Javert and Macri point out that the intermittent or regular use of liquid petrolatum (mineral oil) has been observed to reduce and to maintain the reduction of the prothrombin concentration in pregnancy. Its intermittent use reduced the prothrombin levels in 3 of 9 patients, while daily intake for longer than one or two weeks resulted in a lowered prothrombin in 7 of 10 patients. Apparently the oil interferes with the absorption of vitamin K or it may inhibit bacterial synthesis in the intestine. The oil may even accumulate in the hepatic cells. The evidence at hand suggests that the oral administration of vitamin K to pregnant women may prove of little or no value unless the simultaneous use of liquid petrolatum is curtailed.

Placental Blood Plasma.—Curtis and Worthington state that sterile plasma can be obtained from placental blood in worthwhile quantities. They obtained an average of 103 cc of whole blood from 280 placentas. From 128 cc of citrated placental blood they obtained an average of 70 cc of consistently uncontaminated citrated plasma (25 cc of 2.5 per cent sodium citrate solution being placed in each collecting bottle). The blood is taken from the cord immediately after delivery, prior to the expulsion of the placenta and before any perineal repair is made. The cord is clamped and cut 2 inches (48 cm) from the umbilicus. The collecting flask and cord are wrapped in a sterile towel and held by an assistant, thus preventing any contamination by amniotic fluid. The cord is milked to express the blood while pressure is made on the uterus to fill the cord with the blood which remains in the placenta. A test for syphilis is made on the collected blood. Blood has not been taken from patients whose membranes have been ruptured for forty-eight or more hours or from those with any evidence of a disease transmittable by the mother to the fetus. The authors have used placental plasma in varied clinical conditions. The clinical response shown has been gratifying and there were no local or systemic reactions following its administration. Some of the clinical conditions were hypoproteinemia, acute glomerulonephritis, infections with associated dehydration and shock due to a variety of causes. The authors constructed an inexpensive but satisfactory dehydration apparatus and are dehydrating pooled placental plasma obtained from the obstetric service of another hospital. They feel that during a national emergency placental blood from several hospitals could be transported to central depots for plasma preparation and storage. If their preliminary experiments are substantiated, dried placental plasma used locally to stimulate cell growth may offer a definite advance in the treatment of wounds.

Pulmonary Embolism.—Freston reports the 5 cases of pulmonary embolism encountered at the Roosevelt Hospital within one year; 4 were confirmed at necropsy and 1 patient recovered. A clinical diagnosis was made in only 1 of the 5 cases. Of the 5 patients, 4 were between 50 and 55; the fifth was 37. Only 1 was a woman. Two had had symptoms referable to the cardiovascular system for two and five years; auricular fibrillation was present on admission in the latter patient. The onset was sudden in 3 and less dramatic in 2. The chief complaint at onset was sharp axillary chest pain in 2, precordial burning pain with accompanying knifelike stabbing pain in 1, substernal fulness in 1 and sharp abdominal pain in 1. Dyspnea was present in all on or before admission. Faintness or actual fainting had occurred in 3, localized pain in the lower extremities in 1, hemoptysis in 1, mental symptoms in 1 and maniacal episodes in 2. The physical signs on admission included dyspnea, tachycardia, fever, leukocytosis and cyanosis in all, and polycythemia in 1. Dulness or rales were present in 3; fluid was present in 2 of these. The blood pressure was depressed in 2 and could not be obtained in 1 whose symptoms occurred an hour and a half before admission and in whom a tender popliteal mass led to the one correct diagnosis. In the others shock or phlebothrombosis was absent. Pulmonary embolism, a disease of recurrent multiple embolizations, offers an opportunity to attempt therapy. Efficacious therapy will depend on an accurate diagnosis of the original condition contributing to embolization. Electrocardiographic changes diagnostic of pulmonary embolism were present in 3 of the patients, and 2 had single electrocardiograms that were not diagnostic. Characteristic electrocardiographic changes depend on cor pul-

monale—on metabolic changes in the right and possibly the left ventricle. If clinical collapse does not occur, the electrocardiogram will probably be normal. Conditions that produce right ventricular strain, mitral disease, pulmonary emphysema and so on produce similar electrocardiographic changes and must be ruled out. The temporary and shifting electrocardiographic changes are probably the most significant diagnostic features. The roentgen diagnosis of pulmonary infarction also presents its problems. Confusion is produced by the presence of fluid and of pulmonary congestion, either of which masks the roentgen signs. However, pulmonary embolization with or without infarction is a fairly common condition, often unrecognized when the primary venous thrombosis is not obvious. Thrombosis of the popliteal veins—unilateral in 3 and bilateral in 1—was found at the necropsy of the 4 patients who died. Edema was either absent or slight or it was considered due to the primary cardiac condition.

Endarteritis of Patent Ductus Arteriosus.—Gibb reports an instance of a person who had had an uncomplicated patent ductus arteriosus for fifty years before an acute bacterial endarteritis that had involved the pulmonary artery in the region of the ductus and had extended into the ductus itself and a small part of the aorta superimposed itself. The cardiac valves were free of any bacterial involvement. They showed no evidence of any other disease process except some thickening due to tension and arteriosclerosis. No primary source for this infection other than an extensive bronchial inflammation was found at necropsy. The explanation is that a transient bacteremia arose from such a source and produced the acute endarteritis. Involvement of the pulmonary artery was apparently responsible for the pulmonary infarcts, and probably the extension of the bacterial lesion into the aorta and the associated phlebitis of the pulmonary vein led to the systemic involvement. During the acute disease, a cardiac murmur was not audible. The explanation for this discrepancy was apparent at necropsy in that the entire lumen of the ductus was occluded by vegetations, and it was assumed that but little blood passed through this arteriovenous shunt. Dilatation of the pulmonary artery and pulmonary conus offers evidence for the belief that the ductus arteriosus was patent for some time prior to the endarterial infection. This was further suggested by hypertrophy and dilatation of the right cardiac chambers, indicating the long-standing anomalous shunting of blood. Aside from the usual contraindications to any extensive surgical procedure, the real difficulty in ligation of uncomplicated patent ductus arteriosus lies not so much in the accurate diagnosis of the lesion or in the determination of the optimal time for operation but, rather, in persuading parents to have an apparently healthy young person subjected to an operative procedure with a mortality incidence of at least 10 per cent.

Treatment of Amebic Dysentery.—Manson-Bahr reviewed the records of 535 cases in which *Endameba histolytica* or its cysts were demonstrated by personal observation. Metastatic complications were not considered unless they were accompanied by manifestations of active amebic dysentery. Of the 535 patients, 259 had at some previous time received emetine injections alone or combined with other drugs. The results do not support the assumption that hypodermic injections of emetine are a certain cure. Such treatment controls the urgent clinical manifestations but does not, in the majority of instances, eradicate the infection. Evidence indicates that, far from curing the patient, the practice tends to render the amebas emetine fast and makes final cure more difficult. There were 7 emetine intoxications in the series. Twenty patients had relapses. Among 114 patients treated with emetine bismuth iodide in doses totaling 20 to 40 grains (1.3 to 2.6 Gm.) 7 (6.1 per cent) had relapses. Some proved singularly resistant, and 3 remained uncured after nine separate courses of the drug. Of 13 patients given emetine periodide in total doses from 2.6 to 4.6 Gm., 5 relapsed subsequently. Five patients were given auremetine (an aniline dye and emetine). The toxic effects were considerable, and all 5 patients had subsequent relapses. The results with quinoxyl (oxyquinoline sulfonic acid and iodine), given to 35 patients by mouth and rectum, led the author to believe that it is especially useful in infections resistant to emetine bismuth iodide but not in freshly occurring infections. Eight patients had subsequent relapses. The author believes that a combined treatment introduced by him and consisting of quinoxyl retention enema by day and emetine bismuth iodide by night is most efficacious. The treatment is continuous and is maintained for ten to twelve days. The relapse rate among 361 patients treated in this manner was 3.7 per cent. These refractory patients were eventually cured by further intensive treatments with emetine bismuth iodide and quinoxyl. Follow-up study for ten years and even longer has verified these results. With this treatment it is not necessary to restrict the diet. Seven of the 8 patients treated with acetarsone had subsequent relapses, and there were 5 instances of drug poisoning. Carbarsone proved no more effective than acetarsone, and there appears to be the same danger of arsenical poisoning. Relapses took place as soon as a course had been completed. No permanent cures were registered after the trial of several other drugs. It is evident that in treating chronic intestinal amebiasis the principle of antisepsis has to be maintained.

Herpes Labialis After Sulfapyridine and T. A. B.—According to van Rooyen and his associates, last winter they encountered 27 cases of herpes labialis among patients who had received a full course of sulfapyridine for gonorrhea and 6 cases among healthy nursing orderlies. The herpes developed after a provocative dose of T. A. B. vaccine. The clinical results of sulfapyridine therapy were excellent in that the urethral discharge had abated by the fifth day, so that on the sixth day patients

were given a 0.2 cc. dose of T. A. B. vaccine intravenously as a provocative test of cure. The first 24 of 25 patients who received this dose of vaccine had herpes labialis forty-eight hours later; 16 showed only a slight eruption which cleared up spontaneously without any treatment, but the lesions of the others were severe and a 50 per cent absolute alcohol dressing was applied with good effects. After this the dose of vaccine was reduced by half but again herpes developed in 3 of 6 persons. Thereafter hypertonic saline solution (instilled and retained in the urethra for a short time) was substituted as an alternative, and no further cases of herpes appeared. The conclusion reached was that if herpes labialis is to be avoided T. A. B. vaccine should not be given intravenously to persons immediately after a course of sulfapyridine therapy. This is particularly so during the winter months, when the herpes carrier rate is relatively high. The possibility that the batch of vaccine used became contaminated was explored, but animal inoculation and sterility tests proved that the product was faultless. Finally one of the authors was given 1 cc. of the vaccine subcutaneously without herpes developing. A high virus carrier rate can exist in a community without a high incidence of herpes labialis. In support of this the authors point out that during the winter months they encountered 6 cases of herpes arising spontaneously among healthy nursing orderlies and others in a unit of about 300. All the persons treated for gonorrhea probably carried the herpes virus in their saliva; the large doses of sulfapyridine did not destroy the herpes virus, nor did they cause herpes labialis but the sulfapyridine appeared greatly to enhance the herpetogenic effect of T. A. B. vaccine. The phenomenon was not due to leukopenia.

Renal Complications of Sulfapyridine Therapy.—Laird reports the occurrence of hematuria in 5 soldiers being treated for gonorrhea with sulfapyridine. The clinical picture of the renal complication may take one of three forms: microscopic hematuria in which pain is only sometimes present, gross hematuria usually accompanied by pain which clears up rapidly on withdrawal of the drug and ample fluid therapy and the hematuria in which despite remedial measures there is impairment of renal function which leads to nitrogen retention, anuria and death. These forms may appear as separate entities, but they may, in fact, constitute only progressive stages of the same process. Examples of the mildest form will be detected only by frequent microscopic examinations of the urine. In their absence renal complications will be detected only when they have progressed to the second stage. The author suggests that crystals of acetyl sulfapyridine, precipitated in the renal tubules, pelvis and ureters, produce bleeding, edema and possibly reflex spasm, which may in severe cases lead to ureteric obstruction, hydronephrosis and failure of renal function. Factors which enhance precipitation include intensity of dosage, rate of absorption and excretion, the proportion of free and conjugated sulfapyridine in the blood and urine, the amount of fluid intake and loss and the concentration and reaction of the urine. The most important prophylactic measure is a daily intake of not less than 3,000 cc. of fluid. Treatment of the first and second stages of the complication is simple and definitely effective. In the third stage, a favorable prognosis depends on the immediate institution of ureteric catheterization and lavage. This proved a life-saving measure in 1 of the author's patients.

Toxic Effect of Sulfanilamide Derivatives on Erythrocytes.—In an earlier report (*Schweiz. med. Wchnschr.* 70:786 [Aug. 17] 1940; abstr. THE JOURNAL, Oct. 19, 1940, p. 1410) Moeschlin called attention to the fact that some derivatives of sulfanilamide cause the appearance of anemias in which the erythrocytes contain inner bodies. This observation induced him to investigate in animal experiments to what extent the inner body reaction is determined by the different chemical structure of the various sulfanilamide derivatives. The experiments were made on white mice, and comparatively high doses were used. It was found that unaltered sulfanilamide exerts the strongest inner body reaction and sulfapyridine takes second place in this respect. Other heterocyclic sulfanilamide preparations cause much weaker inner body reactions and produce no real anemia. Use of sulfathiazole never results in the formation of inner bodies, but sulfamethylthiazole causes some inner body reaction. These observations indicate that the toxic action on erythrocytes and hemoglobin, as well as the hemolytic anemias occasionally elicited thereby, is probably the result of the structure of the sulfanilamide derivatives. If the sulfanilamide group can be separated from the compound, its oxidation products seem to elicit toxic effects. Experiments on mice, by revealing the inner body reaction produced by newly introduced sulfanilamide derivatives, will help decide whether the clinical use of the new compounds is likely to become complicated by hemolytic anemia.

*New Test for Functions of Liver. A. Castellanos and J. Beato Núñez.—p. 382.

New Test for Liver Function.—Castellanos and Beato Núñez describe a carotene test for liver function which involves an easy technic, based on the physiology of the liver. The patient takes fruits or fruit juices instead of breakfast. Five or 6 cc. of blood is withdrawn. Then an intravenous injection of 0.2 mg. of colloidal carotene for each kilogram of body weight is administered. Five minutes later blood is again withdrawn. The amount of total carotenoids in the blood is separately determined in the two different blood specimens by the Clausen and McCoord method. The carotene content in the two samples of blood, namely those which were withdrawn before and five minutes after the intravenous injection of carotene, is the same when hepatic function is normal. Any increase of the carotene content five minutes after the intravenous injection of carotene indicates hepatic insufficiency. The authors verified the results by comparing them with those of the classic tests. They studied the relation between the results of the test and the anatomic conditions of the liver by means of puncture biopsy and in some cases by autopsy. They conclude that the test is reliable and better than the classic tests. The article is a preliminary note.

Pituitary (Cushing's) Basophilism.—Fracassi reports 3 cases of basophilism of the pituitary type. The symptoms were typical in all cases. Two of the patients had complete impotence. One had osteoporosis. The menopause was the stimulat-

ing factor for the development of the disease in 1 case. High voltage roentgen therapy on the hypophysis and polyglandular opotherapy early in the course of the disease resulted in the cure of a patient. The patient in the menopause had relief of the menopausal symptoms from administration of an estrogenic substance. The enormous lipodystrophic tissues were removed by lipectomy.

Pernicious Anemia Refractory to Liver.—Budding reports 2 cases of pernicious anemia in which generous doses of potent liver extracts failed to improve the blood picture. The first of these patients had gastrointestinal disturbances and lived chiefly on gruels, excluding from her diet practically all foods which provide the body with nicotinic acid or its amides. The second patient had achylia, which made for deficient absorption. Her diet likewise consisted chiefly of carbohydrates and consequently was relatively deficient in vitamin B₁, since it is known that vitamin B₁ requirements are greatly increased if the carbohydrate content of the diet is high. The patient also had exophthalmic goiter and a high metabolic rate, which is known to increase further the vitamin B₁ requirements. The blood picture of the first patient rapidly improved when nicotinic acid amide was given in addition to liver extract; in the second patient the same result was accomplished by adding vitamin B₁ to the diet. The author concludes that the failure to respond to liver therapy was due to impairment of vitamin equilibrium.

Vitamin K in Pulmonary Tuberculosis.—Bauer calls attention to the difficulties encountered in the determination of the prothrombin blood content and reports studies on it in patients with pulmonary tuberculosis. Some patients showed considerable reduction in prothrombin, which could be temporarily combated by administration of vitamin K. There was no parallelism between the severity of tuberculosis and the prothrombin reduction of the blood. Among 30 patients with a tendency to hemorrhages there were only 8 who had a noticeable reduction in prothrombin. The concentration of prothrombin can be considerably increased by the injection of vitamin K. This increase can still be demonstrated thirty-six hours after the injection. It does not develop with the same rapidity in all patients; in some it is not ascertainable for twenty-four hours after the injection. An especially low prothrombin concentration was observed in 2 patients who for weeks had had diarrhea (amyloidosis, intestinal tuberculosis). Absorption disturbances and amyloidotic changes at the sites where prothrombin is formed are regarded as causes. Irregularity in prothrombin reduction of the examined patients suggests that it is caused by the toxic impairment of an organ (liver). In 10 patients the prothrombin content of the blood was examined in the course of hemoptysis. A reduction could be ascertained in 5, and in 2

of these the hemorrhage ceased when the prothrombin content increased following administration of vitamin K. In 2 others hemoptysis took place in spite of an increase in the prothrombin content even during the administration of vitamin K. In 1 patient the bleeding ceased even before an increase in prothrombin was demonstrable.

Surgical Treatment of Profuse Gastroduodenal Hemorrhage.—Discussing the divergence of opinion regarding the treatment of severe gastroduodenal hemorrhage and the discrepancies in the mortality from this cause, Yudin points out that massive and acute hemorrhages are not due to ulcer in all cases. Finsterer maintained that in 10 per cent of cases massive gastric hemorrhage is caused by disorders other than ulcer; Balfour asserted that this percentage was from 20 to 25 and the author found it to be over 36. The peril to the patient's life is much greater from the ulcerous than from the non-ulcerous hemorrhages. Neither the combination of all conservative measures nor repeated transfusions can save a patient's life if a vessel of considerable caliber has been eroded in a callous ulcer. In most cases resection of the stomach is indispensable. The "exclusion" operation and simple gastroenterostomy are of no use, and in severe cases they would involve an unjustifiable additional risk. Ligation of all vessels around the ulcer may be practical in rare cases, that is, when the ulcer is in accessible parts of the anterior wall of the stomach or the duodenum. Cases in which surgical treatment was given for profuse gastroduodenal hemorrhage may be divided into three groups. The first group includes cases in which hemorrhage had already ceased, collapse had disappeared and the hemoglobin content and the number of erythrocytes were already on the increase. The intermediary stage operations resulted in a mortality of 7.5 per cent (8 deaths in 106 cases). The second group includes 97 cases of emergency operations, the patients being operated on immediately after arrival at the clinic. There were 16 deaths in this group. The third group, in which "desperate operations" were done, includes only cases of severest anemia and intractable hemorrhage. Judging chiefly by the caliber of the eroded vessel, it can be asserted that the patients in this third group would have died if only conservative treatment had been employed. More than half of these patients were saved. During or immediately after the operation, patients with gastroduodenal hemorrhage should be given abundant blood transfusions. Great stores of cadaver blood available at the author's hospital made it possible to venture immediate gastric resection in some cases with an apparently hopeless prognosis. Cadaver blood has proved especially valuable since the drip method has made possible the transfusion of really large quantities. Cadaver blood simplified the problem of donorship for enormous drip transfusions; instead of the blood of four to ten donors being mixed, blood from one to three donors is sufficient for one drip transfusion, and the risk of hemolysis is greatly reduced. Furthermore, since the discovery of fibrinolysis in the blood after sudden death (Skundina), it has been possible to dispense with stabilizers and anticoagulants. It is possible to store cadaver blood without the addition of preservatives.

Etiology of Tick Encephalitis.—Solowjow reports that in recent years a peculiar form of encephalitis has been observed in the forest regions of Siberia. It begins suddenly with high fever, severe headache, vertigo and vomiting. Together with meningeal symptoms, localized symptoms of involvement of the central nervous system develop in the form of paralysis in the region of the upper and lower extremities and in the musculature of the neck and back. The fever persists for four to ten days. Some patients retain permanent atrophic paralysis, par-

ticularly of the proximal portions of the upper extremities and of the musculature of the neck and shoulder regions. The mortality is 30 per cent. The pathologic-anatomic changes in the central nervous system recall descriptions of the Japanese (summer) encephalitis and of the American (St. Louis) encephalitis. The epidemiologic picture of tick encephalitis is characterized by the strict seasonal character. It begins about the end of April, reaches its severest stage the end of May and the first part of June and then declines, only a few sporadic cases occurring after July. The appearance of the tick encephalitis seems to be connected with work in the taiga (swampy forests of Siberia), particularly with the sartige of these regions. The climatic conditions at the time of occurrence are characterized by moderate temperature, high humidity and considerable precipitation. The chief epidemiologic characteristics can be explained by the existence of vectors—that is, ticks of the family Ixodidae. The seasonal occurrence of tick encephalitis follows the period of maximal activity of these ticks. The vector role of the ticks was demonstrated by the detection of spontaneously infected Ixodes persulcatus in the regions where the disease was endemic, by long survival of the virus in artificially infected ticks, by virus transmission by bite and by virus transmission by the transovarian route and in the course of metamorphosis. At the same time that the ticks were studied the possibility of a virus reservoir among the forest mammals was investigated, and it was found that some rodents and insectivores harbor the virus. A considerable percentage of human subjects living in the region where the disease was endemic had a neutralizing antibody content against the encephalitis virus, and the serum of cattle, horses and other animals disclosed the same protection. Tick encephalitis is caused by a neurotropic, filtrable virus which is pathogenic for white mice, monkeys, some rodents and birds. The most reliable method of culturing the virus is transmission to the mouse of a brain emulsion from human beings who have died of the encephalitis. The virus resembles the causal agents of other seasonal forms of encephalitis (Japanese and St. Louis) and differs from them in certain serologic characteristics. The author thinks that the reported studies permit the assumption that the causal agent of tick encephalitis is a specific ultravirus closely related to that of Japanese summer encephalitis.

Parathyroid Tumors.—Bergstrand reports 9 cases of primary hyperparathyroidism. High blood calcium values were present. All the parathyroids of 4 patients were examined and, in 3, more than 1 was appreciably enlarged. In 1 instance it was demonstrable that the adenoma-like new growth involved only one gland. This point could not be determined in 5 cases because the material was obtained at operation or at incomplete necropsy. The author reports a tenth case in which symptoms indicated attacks of acute parathyroid poisoning with disturbances in the cardiac rhythm and blood pressure and gastrointestinal function. Necropsy showed the inferior right and left superior parathyroids to be plum sized and the other two to be more than twice the normal size. Microscopic examination revealed all four parathyroids with large cells rich in protoplasm and free from fat. The newly formed parenchyma in both large tumors consisted of a collection of adenomatous nodules. Such adenomatous parathyroids may exhibit regressive changes similar to those found in the adenomatous goiter. The interstitial connective tissue may increase in amount and become hyalinized, even calcified. Cysts may develop through the collection of follicles dilated by a colloid-like mass or

through softening of degenerated, disintegrating tissue. The study indicates that, in a large number of cases, both the primary and secondary parathyroid enlargement appears anatomically like an adenomatous hyperplasia, analogous to the conditions in thyrotoxicosis. The secondary hyperplasia may be diffuse, but it seems to be able to develop into an adenomatous hyperplasia similar to that in the formation of adenomatous areas of the thyroid. Regarding the supposed primary parathyroid enlargements, many were multiple adenomatous formations in a diffusely changed parenchyma. It is therefore probable that the primary neoplasms in these cases may often actually be secondary to some unknown irritation. If an irritation first produces diffuse hyperplasia and then adenoma-like formations it is easy to understand that the latter would show different degrees of demarcation and different microscopic structures in the same gland. In most cases of osteitis fibrosa the parathyroid enlargement does not resemble a parathyroid tumor but a parastruma. This does not mean that real neoplasms do not exist. The nature of the irritation is most likely a disturbance in the calcium metabolism. That the patients often recover or improve after one or more enlarged glands are removed is no more remarkable than the improvement following partial strumectomy in thyrotoxicosis.

*Clinical Aspects of Traumatic Subcutaneous Rupture of Intestine. N. Liedberg.—p. 325.
*Myxoglobulosis Appendicis. E. Hollström.—p. 347.

Primary Cholangiography.—Liedberg describes his experiences with primary cholangiography and stresses its great value, particularly in the diagnosis of calculi in the choledochus, in the diagnosis of tumors of the biliary passages and in the differentiation between benign and malignant pancreatic compression of the common bile duct. The method is simple and seems to involve no particular risks or disadvantages. However, in some cases pathologic diastasia has been observed after cholangiography, which seems to indicate that the method may have an irritating effect on the pancreas. For this reason, caution is necessary in the injection of the contrast medium in order to avoid great excess pressure, and particularly in cases of acute cholangitis reserve is advisable with the use of cholangiography.

Traumatic Subcutaneous Rupture of Intestine.—Liedberg discusses 52 cases of subcutaneous traumatic intestinal ruptures. Since most of the patients came from rural regions, it is understandable that the kick of a horse was the most frequent cause of trauma (in 32 cases). Hernia existed in 11 (20 per cent) of the patients. In 5 of these 11 the traumatic agent struck the hernia directly; in some of the other cases the hernia indirectly played a part in the development of the intestinal rupture. Among the factors that are of importance for the early diagnosis of subcutaneous intestinal rupture, the author mentions careful analysis of previous history, particularly of the nature and intensity of the trauma; analysis of the nature of the pain; frequent inspection of the abdomen, because increasing muscular tension is of vital importance; rectal palpation, particularly for sensitivity to pressure in Douglas' region; observation of the pulse, because increase in its frequency is a warning, and examination of hernial regions and roentgen examination in obscure cases. If intestinal rupture is certain or highly probable, laparotomy is necessary. Experience indicates that the earlier the operation is performed the better are the results. However, some writers advise against operation during the period of shock. The subcutaneous intestinal rupture can usually be repaired by suturing; resection is necessary only in case of extensive or multiple tears or when long portions of the mesentery are torn away from the intestine. The total mortality in the reviewed material was 36 per cent. Of patients operated on during the first six hours 23 per cent died; of those operated on later 50 per cent died.

Myxoglobulosis Appendicis.—Hollström describes a case of myxoglobulosis appendicis in a man aged 60. The patient was subjected to appendectomy twelve hours after the appear-

ance of the first symptoms. The surgical specimen, together with the globoid mucinous bodies which it contained, is reproduced in a color photograph. The author points out that myxoglobulosis has been designated also as "fish egg mucocoele." Obliteration of the appendix, increased secretion of mucus and absence of purulent bacteria play a part in the development of mucocoele, but the development of myxoglobulosis requires in addition a mechanical factor and possibly a colloid chemical process. The author reviews the theories that have been advanced with regard to the development of the globules of mucus. On the basis of figures cited by other investigators he estimates that myxoglobulosis is observed about once in every 47,500 appendectomies. Of 36 cases of myxoglobulosis described in the literature, in 7 the disease had given rise to pseudo-myxoma peritonei, and in 1 case the myxoglobulosis appendix had encircled a coil of the small intestine, its apex adhering to the cecum and thereby giving rise to ileus. In the other cases myxoglobulosis had produced symptoms of appendicitis, had been found accidentally in the course of operations made for reasons other than suspected appendicitis or had been noted in the course of necropsy.

Relation of Sedimentation, Serum Proteins and Sternal Punctate in Serum Sickness.—In 11 of 13 patients with serum sickness after treatment of pneumonia with rabbit anti-pneumococcus serum and in 1 patient with serum sickness after treatment of diphtheria with horse diphtheria antitoxin Gormsen and Heintzelmann established a definitely increased sedimentation reaction, while 6 of 7 patients given similar treatment without serum sickness showed steadily decreasing sedimentation values. In 2 of 3 grave cases of serum sickness they found severe hyperglobulinemia, and in the third case the maximum normal globulin value; in 1 moderately grave case and in 1 mild case the globulin values were normal. In the 4 most severe cases of serum sickness there was a pronounced increase in the plasma cells in the bone marrow. Both the serum globulin and the plasma cell values in the bone marrow were normal in 4 control patients not given serum treatment and examined in the same stage of the primary disease (pneumonia) as the patients with serum sickness. The authors assume that the hyperglobulinemia, which may depend on an antibody formation, is connected with the demonstrated increase in the plasma cells of the bone marrow. This is seen to support Bing and Plum's theory of the plasma cells as formers of globulin.

Treatment of Inguinal Hernia in Children.—Kjøster and Fix say that inguinal hernia in childhood is congenital and depends on the persisting processus vaginalis (canal of Nuck). At any time after birth the bowel or other viscus may descend into this preformed sac. The treatment is operative. The operations should be performed as early as possible by a simple technic, with removal of the hernial sac and avoidance of plastic surgery, best and most rapidly according to Lorthior's method. Follow-up of 113 cases of inguinal hernia in children operated on according to Lorthior and Czerny showed testis atrophy in 2 but no recurrence. In eighteen inguinal hernias in children operated on by other methods there were 2 cases of testis atrophy and three recurrences. The average time of observation was eight and a half years.

TRAINING OF INTERNS IN THE SOCIAL ASPECTS OF ILLNESS

ETHEL COHEN, M.S.

Director of Social Service Department, Beth Israel Hospital;
Assistant in Medicine, Tufts College Medical School.

AND

HARRY A. DEROW, M.D.

Associate Visiting Physician, Beth Israel Hospital; Instructor
in Medicine, Harvard Medical School.

BOSTON

Since 1929 a plan for the training of interns¹ in the social aspects of medicine has been carried on at the Beth Israel Hospital, Boston.² The purpose of this paper is to present an evaluation of this plan following ten years' experience.

The plan has aimed to develop an appreciation that (1) the practice of medicine is not merely the treatment of sickness but the care of sick persons, (2) the everyday circumstances of life play an important role in creating illness, (3) illness with its accompanying problems often disrupts normal existence and (4) consideration of social factors is consequently an inseparable part of the process of diagnosis and treatment. The objectives of the plan have been met by requiring the senior intern to:

- (a) Acquire comprehensive social knowledge himself about each patient in his ward.
- (b) Discuss these data at regular weekly medical social ward rounds with the resident and the medical social worker assigned to the particular service.
- (c) Share the responsibility for plans for therapy or after-care based on the realities of each patient's social as well as medical needs.

During his six month period as senior at this hospital, the intern studies and treats approximately 300 patients. By the systematic consideration of every patient in the ward in the manner described, he realizes, through the many vicissitudes in the treatment of patients, that there are interrelationships between the

patient's personality, his social environment, his illness and his response to medical therapy. The practice of considering each patient individually in his social as well as his physical aspects becomes an established habit of thinking, persisting in private practice or medical teaching.

A procedure of this sort places on the intern additional responsibility beyond the technical medical study and treatment of patients. It is time consuming. It involves for most interns a new orientation in thought concerning patients and illness, for during most of four undergraduate medical years the student has, with some exceptions, concentrated largely on the physical and scientific aspects of disease.

During undergraduate study, treatment has been viewed usually from the standpoint of drugs, surgery, roentgen ray and other technical procedures. The great amount of technical medical knowledge which must be crowded into the short time available to the students during the latter part of their undergraduate study makes it increasingly difficult for them to see each patient in all his dimensions and with perspective. Instead of the hospitalization period being an episode in the patient's life, it frequently occupies the full range of the student's view. Though patients have been seen by some students with their individual physical and even psychic differentiation, not enough emphasis has been placed during undergraduate study on:

- (a) The patient in his social setting.
- (b) The interaction of the patient's social situation and his illness or disability.
- (c) The patient's attitude toward the situation created by his illness.
- (d) The difficulties involved for the particular patient in a proposed plan of care.
- (e) The possibilities of the recommended plan being carried out.

In certain teaching hospitals, conferences on the medical and social interrelationships of illness in the case of a few patients have been carried out.³ These discussions have been of value in demonstrating to the medical student

the existence of another important phase of medicine. This experience, though valuable, is brief and usually not comprehensive enough to help him with the individual problems he meets later during his internship and in his private practice.

During the internship period the young physician becomes responsible for the care of patients; then the need for understanding sick people and helping them with their problems becomes vivid.

MEDICAL SOCIAL WARD ROUNDS

The procedure that serves at the Beth Israel Hospital is known as "medical social ward rounds" and is conducted at a specified time each week. The resident physician, the senior intern and the medical social worker assigned to the service meet and discuss each patient. The senior intern presents a statement of the social data which he has secured himself in interviews with each patient, including facts relative to home conditions, economic stability and factors for consideration of after-care. The intern is expected to know the type of home and neighborhood from which the patient comes and the suitability of this environment for convalescence. He must know whether the patient has a dependent family or whether there are children at home without care about whom the patient may be worried. The possible existence of emotional factors or conflicts within the home must also be appreciated. In regard to economic stability, he should learn whether or not the patient has financial worries, is unemployed or is in fear of losing his job while ill. From the beginning the intern should realize that he will be asked for advice as to the patient's after-care, and he must therefore consider whether the patient can understand and will follow instructions and whether he will be able to carry heavy housekeeping duties or be able to provide for a special diet or appliance if necessary. Also he should study the possibilities of the need for adjustment of occupation or of school work. In addition to these social data, the intern describes the medical aspects of the patient's illness during medical social ward rounds. This includes a statement of the patient's physical and mental condition, the probable duration of hospitalization, the outlook for the immediate present and for the long range view, a statement relative to ability to resume activity or need for its limitation at home, at work or at school, and recommendations as to the type of care that the patient will require following discharge from the hospital.

This material is discussed by the three participants in this procedure, and a decision is made as to which of these patients present problems which the medical social worker should take

up for further social study and case work service. During these rounds the medical social worker also reports on the developments in the patients still in the wards whose problems had been taken up on previous rounds. After all the cases have been presented, they are reviewed briefly to determine which seem to call for immediate attention and which may be deferred. This joint evaluation and discussion, valuable for its own sake in promoting further thought on these problems, is necessary also because of the social service department's policy of limitation of intake and selection of problems accepted for service.

In the intervals between these weekly rounds, the intern, and frequently the resident and the medical social worker, have numerous informal discussions concerning progress in the patients under their care. In addition, the interns often request the medical social worker to join a discussion of the patient's condition and future care with the relatives after the regular ward visiting hours.

The medical diagnoses, prognoses and general questions of after-care are, of course, taken up by the visiting staff on the regular daily morning ward rounds with the interns in attendance. The data secured during these daily visits with the staff physicians form the basis for the material which the senior intern presents at the medical social ward rounds. The visiting physicians are occasionally consulted by the senior intern and the social worker in special types of cases. These include the following situations:

(a) When the recommendation is made for a radical change in the patient's work or general way of life.

(b) When the medical social plan is not accepted by a patient seriously ill and a safe compromise is needed.

(c) When social plans involve large expenditures of money, either by the patient or by the community, for chronic or convalescent care.

(d) When the diagnosis is still in doubt, and the patient does not require further hospital care for an acute condition but home facilities seem inadequate.

(e) On a small miscellaneous group of complex and delicate problems which require more mature judgment.

It is to be noted that this procedure has been carried on in both the surgical and the medical ward service. Initially, we accepted the common opinion that the surgeon's preoccupation with the technic of operative and postoperative care precludes interest in the social and emotional aspects of his patients' illnesses. We no longer hold this view. Some of the most thoughtful, imaginative and responsive men have been interns in surgery. Despite the exigencies of urgent operations and the unexpected post-operative emergencies, surgical interns have served as well in this procedure as the medical interns.

The Learning Process Through Joint Thinking and Discussion Between Intern, Resident and Social Worker.—When the intern begins his experience with medical social ward rounds he is apt to disregard social data as unimportant and to dismiss certain patients with the remark "there is no social problem here." He may believe this because of his inability to evaluate the social history he has secured. The social worker, however, appreciating that the intern has not yet had the experience to justify this statement, asks him what he found the situation to be. Sometimes the intern has adequate information and believes that he is as able to make a judgment as valid as the social worker's. However, because of the difference in training and professional orientation, the same facts often have different significance for the intern and the medical social worker. Two brief examples are presented here for illustration:

CASE 1.—A man aged 42, a moving picture operator, was unable to resume work because of severe malignant hypertension. He earned, when employed, \$90 a week. He owned the home in which his wife and four young children lived. The intern believed that an intelligent patient of this economic level required only medical care from the physician with no further concern by the physician or any one else. The serious nature of the illness, the patient's feelings about his situation, the need for the patient's adequate care following hospitalization and the question as to the potential dependence of his wife and young children during the terminal phase of the illness and afterward were the implications which impressed the medical social worker from the facts as finally related by the intern, rather than the income and home ownership. A subsequent interview with the patient and family revealed the patient greatly worried because of heavy debts, no savings, threat of losing his heavily mortgaged home, dependence on friends and relatives and serious family friction and distrust.

CASE 2.—The intern learned from a ward patient that she was a dietitian, that her son was in a private school and that she had earned \$135 a month, but had not worked for five months because of illness and was living at a private club. The medical diagnosis was not clear and, since exploratory operation was being considered, a period of convalescence would be needed before she could return to work. The intern thought it unnecessary to spend any time beyond the strictly medical care of this patient because "she presents no social problem." He considered \$135 a month a large income and assumed the existence of other income or savings for the maintenance of a son at a private school. More significant to the social worker even than the patient's wages was the five month period of unemployment because of illness. Also, she wondered what kind of "private school" would take a boy whose mother had not earned even her usual \$30 a week for five months. Additional study revealed the facts that the "dietitian" was a domestic employed at \$10 a week and that her illegitimate son was in an institution under the care of a social agency. The club which the intern named as the patient's home was known to the social worker as a place where unemployed working women could procure food and lodging for a temporary period. There was no possibility of convalescent care there.

It is clear that the intern had not been aware that the "facts" lacked inner consistency, nor

had he been concerned with the possible reason why the patient felt it necessary to present herself in this light.

At times the intern may present social data without understanding the significance of the data for the particular patient discussed. The social worker asks for more information which would apply particularly to the age, marital status, occupation, responsibilities and attitudes of the individual patient. She may raise questions about the medical data, such as What is the significance of this illness? Is it progressive, self limited or will it be quiescent for a period and become reactivated later? How does the type and extent of the illness affect a particular patient? The self-limited illness in a given patient may present no special problems which the patient or his family cannot manage themselves, but a chronic progressive illness of the same patient and with the same social situation may change the pattern of life of the patient and his entire family.

Through such continuous questioning the intern becomes increasingly aware of the need for relating the patient's social situation to the particular medical problem. The social worker shares with the intern the knowledge that she has gained in her social study of a particular patient through interviews with family, social agencies, school or other relevant sources. Her data may either confirm his social history, elaborate on it or correct it. Her contribution will be the result of her skill derived from training and experience in her own specialized field of social work. In time, the intern gains appreciation of the meaning and interrelationship of the various social and medical data. Just as the trained medical social worker through experience gains an appreciation of the prognosis and possible plan of treatment in certain illnesses, so does the intern in the course of time develop skill in gathering and evaluating social data and an awareness of the inherent relationship of potential social factors with certain medical diagnoses. This process, which was at first conscious and deliberate with practice, becomes less conscious and more habitual.

Usually one of the foremost objectives of the intern is disposition of the patient, making possible new admissions and new medical experiences. While this primary objective of the house officer is being furthered by the social worker indirectly, the intern is becoming habituated to the consideration of the social factors of each patient.

The resident contributes to both intern and social worker from his longer experience and greater knowledge. The intern and social worker each has his own particular function and professional skill, but neither can carry out his function in the care of the patient completely

by himself. At certain points and many times their functions are interrelated and merge. They must think and practice in coordination and harmony.

The development of understanding, insight and skill is a gradual process. The rate of progress depends on many factors within the intern and within the medical social worker; their ability to "give and take," to interpret to each other the special knowledge each has and to accept each other as professional workers sharing in the study and care of the sick.

Subjects Discussed During Medical Social Ward Rounds.—A wide range of subjects is covered in the course of the discussions during rounds. These relate to the particular problems encountered or the obstacles to the carrying out of the plans agreed on. Some of these subjects are:

1. The description of the elements of a home maintained on a marginal or substandard income.

2. The effects on the patient's immediate health and on family life of overcrowding, inadequate equipment, insufficient heat, light and air.

3. Description of various community resources, their policies and the conditions of acceptance for service or care.

4. The absence of necessary resources, the consequent need to devise substitutes and to consider relative advantages or disadvantages of several possible alternatives for the case in question.

5. The influence of the various racial and cultural traditions and customs on the patient's and family's relationships to each other, to certain kinds of illness, to hospitalization, to home care, to diet and to dependence.

6. The influence of emotional strain, economic inadequacy and other unfavorable social conditions on the illness.

7. Analysis of factors for consideration in securing "complete rest" or "modified activity" for a mother with small children; for young or old persons living alone in a rooming house or hotel and like situations.

8. The unfavorable effect on the sick person of demands that unwilling relatives provide care, as contrasted with the more favorable opportunity for the patient's improvement when the responsibility for care is assumed in adequate community resources.

9. The need to understand the forces operating in the so-called uncooperative patient who demands discharge against advice; the hospital's responsibility to see that the patient may know how to secure sound medical care elsewhere or to allow the patient to return to the hospital again if he wishes.

10. The importance of ascertaining the physical and emotional health of relatives who will bear the burden of care for seriously handicapped or chronically ill patients.

11. The importance of weighing both the probable psychologic and the economic effects on the individual patient of recommendation to give up work entirely or to change radically his occupation even in the presence of a chronic progressive illness.

12. Appreciation of the length of time needed by the medical social worker, community social worker or family to mobilize resources, even when all are working at maximum speed, and the variation in amount of time needed because of varying intelligence, emotional maturity of patient or relatives and financial resources.

13. The hospital's responsibility for care of the patient as its major responsibility, as well as the advancement of the intern's opportunity for handling a maximum number and variety of patients.

These by no means constitute all the subjects discussed during rounds or in the intervals between rounds. All these concepts and undoubtedly many more are the subject of discussion in all hospitals where trained medical social workers and interns work together. The significant difference in the plan here described is that these discussions are habitual, regular and frequent and include a large number of patients. The cumulative knowledge and the increase in understanding derived from experience with a large number of cases tend to develop in the intern the habit of considering all his patients in terms of the nonmedical aspects.

PARTICIPANTS IN THE PLAN

The Intern.—Interns vary considerably in the rapidity and manner in which they learn to appreciate the importance of social factors in disease. This is because of differences in personality, interest in people, administrative ability as senior wardman, degree of confidence relative to medical knowledge, ability to accept questions from the social worker which the intern may not be able to answer and to acknowledge the need to consult the visiting physician. Interns with whom representatives of other departments have difficulty will usually present difficulties in relations with the social worker.

The integration of previously acquired scientific knowledge with newly acquired social concepts may at first be difficult. It is definitely influenced by the intern's previous social experience and in turn often involves change in his social outlook. Problems of patients often stir up problems in the intern's own life, producing subjective reactions that influence his thought and activities concerning the patient. For example, some men who have earned their way through school, college and medical school, carrying family burdens as well, at first believe that every one else could help himself if he "willed" to do so. Not "willing" to do so, the patient is therefore unworthy of help from society. Other men coming from an economically well favored environment initially may have no appreciation of pain, want, loneliness, strife or of the dread of dependence, while others from similarly well favored backgrounds may be overprotective and urge assistance even when none is desired by the patient. For many patients independence and self maintenance, even on a meager scale, are their most treasured possessions.

The Resident.—Brief reference has already been made to the role of the resident. In the

organization of the Beth Israel Hospital, the intern is responsible to the resident. The resident's presence during medical social ward rounds provides the medical social worker with support and authority which is especially necessary in the early period of each senior intern's experience. The resident can often influence the intern's evaluation of the patient's condition, prognosis and needs following discharge from the hospital. From the resident's comments the social worker likewise gains considerable medical knowledge and understanding.

A resident indifferent to this aspect of medical care may be a real handicap to both intern and social worker, while an interested resident can greatly further its development.

The Medical Social Worker.—The high degree of cooperation involved in this kind of teamwork requires tact, stability and resourcefulness on the part of the social worker. Her contribution will be more effective as she learns how to share her specialized knowledge with the intern. She must be mature enough emotionally to accept some interns' reluctance at times to share medical data sufficient for her comprehensive understanding of the total medical situation and their unwillingness at times to accept her interpretation of emotional and social factors and their relationship to the particular patient's medical problem.

Our experience has demonstrated that the medical social worker participating in this procedure should be a well prepared, professionally experienced and mature person. She must be secure in the knowledge of her own function and of the philosophy and concepts of present day social work. Unless she is able to express her ideas clearly and to demonstrate them convincingly through her practice, she will have little success in influencing the young physician's point of view or in stimulating his interest in a broad concept of medical care. She must know how to work understandingly with the intern whose authority as senior wardsman is important to him but whose theoretical knowledge has not yet been tempered by professional experience. The knowledge acquired over a period of years by medical social workers from close working association with physicians in a procedure of this kind increases their usefulness to the patient, to the hospital and to other community agencies.

The advantage of having the same medical social worker assigned to these ward rounds for a long period of time is considerable. Opportunity for cumulative learning and understanding of the intern's problems and psychology can be attained only by continuous experience with many different interns. Because of the periodic changes of interns, the possibilities of the maintenance of this system of rounds is greatly

enhanced by continuity in service of the same medical social worker. As each man completes his training period, he is succeeded by another intern. The resident may serve for one year only. Thus, the entire process is recreated anew every few months. The medical social worker is the one practitioner in this team who, because she is a permanent staff worker, can promote the purposes of an integrated service to the patient.

EVALUATION BY THE GRADUATES OF MEDICAL SOCIAL WARD ROUNDS

Throughout these years we have been formulating our own conclusions as to the values of the plan from our observations and indirect participation, but we desired in addition the testimony of men who had actually had the experience and had reacted to it in various ways. A conference was held with twelve graduates. Their comments were of such interest as to stimulate us to elicit the reactions of the entire number of interns and residents, fifty-three in all, who had participated during the ten years that the plan has been in use. The questionnaire method was decided on as the most practicable because many of the graduates were practicing in various parts of the country.

As interns, these fifty-three men were graduates of a number of different medical schools. They represented a variety of professional interests, skill and ability.

It was expected that some of the graduates would respond negatively to the rounds because of the amount of time and thought required in the whole process and because of certain psychologic reactions or social points of view. In order to secure full and free expression of opinion and comment, the questionnaire, worded so as to encourage negative replies, was sent out over the signature of the medical author only.

Subjects Included in the Questionnaire Sent to Graduates.—The graduates were requested to discuss the parts of the procedure to which they objected and to state whether they found it difficult to secure social information from the patient. They were asked to evaluate which aspects of the plan they considered of value to the patient, to the hospital and to themselves during their period of training and whether the experience had been of value to them in their private practice. The graduates who are now teaching medical students were asked to describe the method by which they bring into their teaching their consideration of the patient as a whole. They were also asked to suggest changes for improvement of the plan and to comment on any point not covered by the questionnaire.

Analysis of the Replies to the Questionnaire.—Replies were received from every graduate, in most instances within a week. An analysis was

made of the distribution of graduates as to present geographic location, field of practice and medical school teaching affiliations and is recorded in the accompanying tables.

There was considerable agreement on many points by both the medical and the surgical

graduates. A selection of their comments for this paper was made on the basis of characteristic replies or of evidence of unusual understanding of the aims of the plan.

1. Parts of the Procedure to Which Objections Were Raised: Seven medical graduates objected to the time taken up by the rounds from their other responsibilities. Two of these men believed that there was no advantage to be gained from rounds which could not be as well accomplished by some other technic. One of the men who had objected in the beginning that it was time consuming with experience changed his point of view, as it then "seemed a worth while expenditure of time."

Four surgical graduates, though they did not object to any part of the procedure, wished that they could have had more time to give to it.

2. Difficulties in Securing Social Information from Patients: Six medical and four surgical graduates found it difficult to secure financial data from the patients. This was the only point about which they thought that they had had difficulty in the early part of their experience. This, they believed, without substantiating evidence, to be due to the patients' fear that the physician's knowledge of their financial circumstances might in some way adversely affect their care in the wards. A few graduates thought that the difficulty in securing accurate information was due to the patient's pride or his desire to conceal his economic state. Undoubtedly, practice in interviewing increased their skill, since the graduates who found this a problem at first stated that it became less difficult with experience.

3. Values to the Patient: All the medical and surgical graduates felt that the plan was of value to the patients. They mentioned the importance of appreciation of the social and economic background of the patient so that their therapeutic procedures and recommendations would be feasible. The patient was considered in terms of his total disability rather than in terms of pathologic lesions. Often asking the patient for social information opened up a general discussion in which the patient revealed emotional conflicts and their causes. It made possible a better handling of convalescence and the care of chronic disease while at home. Adequate after-care was secured for a great many patients who otherwise would have returned to the hospital in similar sick conditions.

Patients benefited by the interns' increased realization of the social implications. This was particularly true of those interns who had not been exposed either by their own personal experiences or by observation to the effect of low economic status, environment and adverse relationships on people. The patients appreciated the hospital's interest which extended beyond the period of hospitalization.

4. Values to the Hospital: All the medical and surgical graduates felt that the plan was of distinct value to the hospital. An adequate plan for after-care frequently reduced the period of hospitalization and eliminated unnecessary readmissions, thus assisting the hospital in maintaining its status as an institution for the care of acute illness and in rendering maximum service to the community.

5. Values to Graduates During Their Period of Training: All the medical men believed that it had value for them during the period of their training in the wards. All the surgical graduates felt that it had value to them excepting one,

and he wasn't sure. The typical replies from all the graduates indicated that this experience increased their understanding of the patient, that it removed the "case" attitude; that it was a valuable adjunct in the handling of patients not obtainable from textbooks or lectures. It taught them how to plan the care of patients following hospitalization which had not been included in their training up to that time and gave them a long-term view of every patient's

illness. It gave an excellent background for evaluating the factor of the human and environmental equation in the causation, aggravation and recrudescence of functional and organic symptoms. It tended to establish a closer interest in the patient as an individual, enabling the

intern to learn more from each problem, and at times gave the clue to the diagnosis in psychoneurosis and in other personality problems. Also recommendations which were impossible for the patients to carry out were eliminated. Various types of after-care were learned and the difficulties encountered in arranging for them.

6. Values of the Experience to Graduates in Their Private Practice: All the graduates expressed the view that a greater understanding of the patients resulted from the experience. Also, it "developed the human touch appreciated by patients" and emphasized the great part economic factors may play in illness and in the recovery from illness. By acquiring a greater understanding of the patient, some of the graduates believed that they had been rewarded both by a broadened experience and by a greater financial return.

7. Method by Which Graduates Bring into Their Teaching Their Consideration of the Patient: Among the replies from medical graduates now engaged in teaching medical students were included the following methods: Insistence on complete social data for better understanding of the presenting symptoms and intelligent treatment; consideration of disposition of the patient as active therapy not as a finale to a temporary episode; the need for knowledge of the patient and his environment so that plans for disposition will be "feasible, adaptable and profitable."

One of the graduates wrote:

In my third year teaching on the medical wards in the afternoon, several patients with the same diagnosis are discussed. The social aspects are considered, not as a separate entity but as part of the patient's history. When a patient's history is taken, he is not first asked about his pain, but what he does and how he lives. As the patient's history reveals economic insufficiency or unemployment or strain, then the students are told about the failure of medical therapy alone in given cases where these social elements are an important

factor. For example, in a patient with a gastric ulcer, the unmet need for special diet, or family troubles may prevent the medical treatment from becoming effective. As some of the patients are taken up several times, the students then see that their fancy therapy doesn't work.

8. Changes Recommended and Comments: Practically no suggestions for change were made excepting that one or two graduates suggested the expansion of the rounds to include the visiting physicians. Several of the graduates associated with other hospitals commented on the greater possibilities for service to patients by the procedure of medical social ward rounds in which they had previously participated and the lack of which they now regretted.

CONTRIBUTION OF THIS PLAN TO PREPARATION OF MEDICAL TEACHERS FOR TEACHING STUDENTS THE SOCIAL ASPECTS OF ILLNESS

During the early years of the use of this plan of training interns both of us were responsible for teaching fourth year medical students the social aspects of illness. However, as the interns and residents graduated and received medical school teaching appointments, a number of them became teachers in the seminars on social aspects of illness to fourth year students of Harvard and Tufts medical schools assigned to Beth Israel Hospital. The schedule for this teaching is so arranged that the graduates responsible for the regular medical teaching in the wards also conduct the conferences for the teaching of the social aspects of illness later the same morning. In both aspects of this teaching, as a result of their earlier training, the graduates quite naturally and without conscious effort discuss the patient's illness in terms of the particular patient's individuality. The medical social author of this paper has participated in all special conferences on the social aspects and has been greatly impressed by the understanding and enthusiasm which these physicians have brought to this teaching.

In addition to the number who have taught fourth year students, there are other graduates who are assigned to medical teaching for second and third year students. The third year students at the Beth Israel Hospital work in the medical clinic of the outpatient department, where for the first time they take histories, examine patients, make diagnoses and suggest treatment. The Beth Israel graduates who serve as instructors put considerable emphasis on a comprehensive history, stressing the relationship of the social and personal items in the history to the past and present illness and physical examination. As the instructor senses a social component which has bearing on the health situation, he discusses this with the students himself. When the patients present complex social problems or situations which require social assistance, the instructor suggests that

the student take the problem up directly with the medical social worker. She may elaborate on the less obvious social implications of the problem at the time the patient is referred to her. Later, after she has studied the situation and given some case work service, she will report her observations to the student and the instructor. At times this presents an occasion for discussion of broad questions of social import in relation to illness. All of this is carried on informally and as naturally as the student is taught the use of laboratory aids to diagnosis.

It is believed that the training which the intern receives in medical social ward rounds offers a logical opportunity for preparing potential medical instructors for their future responsibilities.

SUMMARY

Medical social ward rounds, as carried on at the Beth Israel Hospital, constitute a regular part of the official duties of the senior intern, resident and medical social ward worker.

As a tested practice over a period of ten years, the plan has been evaluated by the authors and all fifty-three graduates who have participated in the procedure during this time. Of the fifty-three graduates from "straight" internships or residencies, thirty-four were medical and nineteen were surgical. They are located in twelve states. Twenty-seven graduates are teaching in seven medical schools, nineteen medical graduates in five schools and eight surgical graduates in three schools.

Principal among the special features of the plan are:

(a) The responsibility placed on the intern himself to secure a comprehensive knowledge of the patient's social as well as his physical history, so that he may be able to think of the patient in terms of his totality. This replaces the more usual hospital practice in which the social worker takes the responsibility for securing social data.

(b) A review by the intern with the resident and medical social ward worker of the data he has learned, considering each sick person in terms of his own personality and environment.

(c) Discussion by the medical social worker with intern and resident concerning significant social implications unrecognized or unappreciated by the intern to which the trained experienced medical social worker contributes insight and understanding. This aims to broaden his view to consideration of illness and disability beyond the more limited concept of diagnosis and disease.

(d) Sharing by the intern with the medical social worker in the selection of patients with complex social or emotional problems requiring further social study and treatment by medi-

cal social workers or community workers equipped to provide other specialized services.

(e) Sharing with the medical social worker in planning for care of the patient following hospitalization. This furthers his understanding of obstacles within the patient or his surroundings which may arise to prevent or delay execution of both simple and complex recommendations for treatment. From this cumulative experience with a large number of patients, he derives a broad knowledge of community life and its resources or lack of resources for health and social welfare.

The experience derived from medical social ward rounds has been of great value to most of the graduates as a preparation for the realities of private practice.

It has provided an unusual opportunity for the preparation of physicians for teaching medical students.

Recognition is given to the periodic change of service of interns and residents in a teaching hospital. The emphasis must be kept on the training or educational aspects of this procedure. Once initiated and developed, this plan cannot be left to progress by itself as a tradition. It must be recreated anew with each new resident, intern and medical social worker. Therefore, the maintenance of medical social ward rounds as a service and as a training opportunity requires the enthusiasm and sustaining interest of physicians and surgeons of senior rank and of the director of the social service department.

In the ten years of the development and maintenance of this procedure, difficulties were encountered. Most of these were overcome through increased experience and professional maturity on the part of the participants. Therefore, it is believed that teaching interns the social aspects of illness by medical social ward rounds has proved to be a valid method. Further use of the method will develop deeper understanding of the problems involved and may indicate adaptations which will enhance its value.

Unpleasant Facts.—There are unpleasant facts which, as physicians, we are compelled to tell patients and their families, and it is my feeling that when the occasion arises they should be told gently, yet frankly and honestly; time should be taken to make all necessary explanations and to allow for whatever reactions may ensue to subside. One should assume the position of the recipient and should conduct himself with patience, sympathy and tact. Indeed, it would probably be excellent training for every physician if at an early period in his career he could be a patient himself, with a fairly major condition, and in this way obtain the viewpoint of the "other side." Obviously, it would be impossible for every physician who is specializing to be a patient in his own specialty but, on the other hand, this is not necessary, for the essentials of physician-patient relationship are constant in all branches of medicine and the desired end would be obtained.—Douglass, Louis H.: *The Patient*, Bull. School Med., Univ. Maryland, July 1941.

Digests and Reviews

A MEDICAL STUDENT'S VIEW OF THE FUTURE OF MEDICAL EDUCATION

Prepared by Donald McDonald, B.A., of Oxford, at the request of the British Medical Journal and published in that periodical Sept. 6, 1941. The following version is slightly condensed.

In the past the wider problems of medicine have been the hobby of more or less eminent members of the profession who are now retired. Today, sudden and violent change has become such a part of our daily life that every one takes note, and the future has become the vital concern of every one. As a sign of this, meetings of medical students from schools all over Britain, which were unknown ten years ago, this year gathered almost three hundred students at Cambridge, organized as the British Medical Students' Association. They discussed problems in every sphere of medicine; but, because the student of today is the doctor who will have to solve these problems tomorrow, and because the education he receives will make or mar his success, medical education was held to be the most important link in the chain of medical planning.

The first and yet most vital problem is the actual entry into the medical school. No one can doubt that the present methods of selecting medical students are haphazard. A father's sentimentality, a desire for a safe job, almost any reason except a desire to serve the community is good enough provided there is enough money for the initial heavy expenditure. Medical schools have to accept such students as a source of income, using a very few scholarships as a means of advertising. The solution clearly must lie with the provision of a vastly increased number of scholarships. Only then can students be chosen because they will make good doctors, which requires temperamental as well as intellectual qualities, and not for any other reason.

THE CURRICULUM

The medical curriculum is long and arduous. This is inevitable because the subject is vast and the doctor needs to be efficient in every branch of it; therefore no one complains about its length. On the other hand, there is much that is useless and irrelevant which needs to be pruned away. The result of this will not be to shorten the whole course but to allow more important subjects to be introduced. The war-time need of getting doctors as quickly as possible introduces an important factor into immediate considerations of the question but will not alter the long-term view of what is felt to be desirable. The premedical course in the

elements of the physical and biologic sciences needs drastic revision, for it is poorly presented, uninformative and a dead weight on the early enthusiasm of the student. Although its aims are praiseworthy it is still planned, as in olden times, for the student who read only classics at school and even possibly took a classical degree before proceeding to medicine. Today that is true of but few, and certainly specialization at school should not be so advanced as to exclude any one's reaching university standard from the elementary knowledge of physics and chemistry that is required. In the meantime the university teaching in these subjects could be much more imaginatively related to their application in medicine. With regard to biology the position is different. A sound understanding of the behavior of living organisms in general is essential for the doctor, but the manner of presenting the subject is not the best. Botany is still based on the needs of the doctor who dealt directly with medicinal herbs. Zoology is planned on the huxleian idea that evolution was in a single line and that the study of lower types will lead directly to an understanding of man. In practice this has led to the student's being required to know details of animals which are the failures, the dead ends, of evolution. Man is the simplest mammalian type and is easier to understand than other species which are highly specialized in one direction. Therefore the comparative anatomy learned at this stage is actually much better introduced with human anatomy. A course in general biology orientated to the special point of view of the doctor is required, and this should include the principles of heredity, the evolution of behavior, which is necessary for an understanding of psychology, and also ecology—the study of animal communities—leading on to sociology. In recognition of the fundamental importance of this course, it should be taught by the best and most mature teachers. A course of this type is given in America and is found to be highly successful. Another plan would be to imitate the American method, in which a general university degree is taken before starting medicine; again the lengthening of the time as a student would be irksome to most.

TECHNICAL TRAINING

Although many criticisms are made of the way in which anatomy and physiology are taught, particularly as the mass of detail to be learned is burdensome, they are not always justified, for the future doctor has to know the details of human anatomy. The important question is to ask whether this essential knowledge is taught in the best way. The

answer is definitely in the negative. In the first place, the two main subjects, anatomy and physiology, are taught as if they bore no relation whatever to each other, with the exception that, by a peculiar English custom, histology lives in the same building as physiology. The geographic separation of the dissecting rooms has created an apparently insuperable obstacle in the relation of structure to function. A little cooperative discussion could surely solve this problem. Anatomy is traditionally learned by mnemonics—which means without the cooperation of the intelligence. To some extent students are to blame, because there are many progressive anatomists who strive against this degradation of their subject. But the students in turn are ruled by the examinations and the unknown quantity of the external examiner, so that progress in an isolated school is extremely difficult. It has already been mentioned in this connection that comparative anatomy illustrates and makes human anatomy more clear, and with this embryology should be included: both these subjects, which introduce a rationale into anatomy, are much neglected in present teaching. This is not a plea for pedanticism but is of real practical importance; for anatomy learned intelligently can never be completely forgotten, as can that learned by rote.

The teaching of physiology is, on the whole, much better but once again suffers from a tendency to cram certain facts without understanding. In this subject the defect is more important, for, while anatomic detail remains the same for successive generations, physiology is advancing at a fast rate. Therefore it is essential, if his medicine is to be based on sound physiology, that the future doctor learn it in a scientific flexible way with an understanding of past developments that will enable him to keep track of its advances in the future. In the past only Oxford and Cambridge have specifically set out to do this, and they allocated a year to take an honors course in animal physiology. It was popular in spite of the extra year required, which means that its value was appreciated by the students. Now, in the interests of war, this course has been omitted; but in the future its example should be taken heed of, if not in the formal sense of a year's course at least in the way that physiology is taught. In addition to the intellectual approach the course provided excellent technical practice, of which the best was in mammalian physiology, for this is the only chance students get of handling living material before they have to deal with patients on the operating table.

The teaching of structure and function together is an obvious need. Equally essential is the comparison of the diseased with the

normal. While the student cannot do every subject at once, it must be remembered that the preclinical subjects are taught for use in clinical medicine, so that the introduction of clinical material early in the course illustrates and gives direction to the learning of anatomy and physiology. Study of the nervous system is the outstanding example in which function and anatomy need to be taught together and then directly applied to the neurologic case. Instead of this, each part is taught independently, in different places, at different periods, with a great amount of repetition which is a waste of time.

CLINICAL TEACHING

In clinical teaching the most frequent criticisms are directed against rather different objects. This is because the whole environment changes from an academic to a professional one. The student is told that the objects of his studies are, first, diagnosis; second, diagnosis, and, third, again diagnosis! But the student, while never denying its importance, wonders if this is quite enough. Has he really done all that he can if he listens to a tuberculous lung for six months and then, having diagnosed a healing condition, sends the patient back to the slums he came from? Is it really sufficient to study 10 cases of children with rheumatic heart disease without observing that they all come from a district with notoriously damp housing? No, it is not enough; and the fact that students in conference bring such criticism up again and again shows that they feel frustrated by the present scope of their teaching. The teaching of preventive medicine is a widespread and urgent demand which is neglected almost everywhere. Public health lectures, as given at present, deal with the legal aspects of sanitation and no more.

The great majority of students are going to be general practitioners, forming the vanguard of any advance to improved health for the community the profession is going to make. On them will rest the responsibility of diagnosing disease early. Yet the material they are taught with is still almost entirely "interesting" cases of rare diseases or with advanced physical signs. This has some justification, for the specialist naturally collects cases in his own specialty, and the loudest murmur is the one for the beginner to listen to. On the other hand, the senior student who has learned to recognize physical signs can apply his knowledge in clinics, which is the nearest thing to general practice that hospitals provide. Outpatient clinics are fairly good for this purpose if they are not overcrowded, but municipal clinics that some London students go to are better, and the dispensary system in Scotland probably best of all.

THE MILDLY NEUROTIC PATIENT

Another major problem in general practice is the maladjusted, possibly mildly neurotic, patient. A field in which a great deal of good can be done, it is almost entirely neglected by present day medical education. Psychology consists of a few lectures in the major psychoses, illustrated by the most amusing inmates that the mental hospital can produce. This is a most important omission that can and should be rectified. Also in general practice in industrial centers diseases due to working conditions and industrial processes are constantly being met, yet training in recognizing them is confined to possibly two lectures in a public health course. In all these ways could medical education be more closely related to the needs of the doctor after qualifying.

TEACHING UNITS ARE TOO LARGE

The manner in which teaching is carried out falls short of the ideal. Units tend to be much too large for the best results, as, particularly in the wards, the information does not reach many of the listeners, and there is no opportunity at all of asking questions or taking part in discussion. Lectures are often compulsory, in which case the student is denied even the simple criticism of stopping away, and the lectures may become slovenly as a result. Reading from textbooks has been redundant since the invention of printing. During the last two years, when many schools have been evacuated, it has been found that the formation of seminar groups between teacher and students, with free discussion, has led to the most successful results. At the same time the ability to criticize lecturers has resulted in improvements. Thus the formation of staff-student groups to discuss the organizational problems in a school is found to be effective from all points of view, revolutionary though it may seem. The other alternative suggestion is that the staff of a medical school should have had a pedagogic training or at least be chosen for teaching ability rather than for research. Many feel, however, that this would kill any scientific life in the teaching through replacing scientists by orators, for if the research worker is good he will have such a clear idea of his subject that he cannot talk badly about it. The way forward shown by helpful mutual criticism between teachers and taught seems to be by far the most promising.

The provision of smaller teaching units also enables students to get far more practical experience of the various techniques, such as lumbar puncture and intravenous infusions, that he will need to be able to do as a doctor. Opportunity for this varies greatly in various medical schools, and it cannot be doubted that the complete divorcement of the student from practical work is very bad. On the other hand

there is often required a tremendous amount of attendance at operations which in fact can demonstrate nothing to those more than a yard from the operative site. Perhaps most important of all is training in casualty work, for minor surgery plays a large part in a practicing doctor's life. The aerial warfare of today makes it doubly important; in fact, the teaching of this subject has been greatly extended since the beginning of the war, but there is doubtless still room for improvement in some places.

CONCLUSION

A great many of the points mentioned can be easily changed by local adjustment, and usually the members of the staff are very willing to accept suggestions for improvement. Broadly, however, the aims of medical teaching can only be altered so that they fulfil the needs of the doctor and enable him to serve the community to the best of his ability, on a national scale. The British Medical Students' Association is going to present, by invitation, a memorandum to the Planning Commission set up by the British Medical Association, and by this means it is hoped that the necessary changes will be effected.

THE ORIGIN AND PURPORT OF UNIVERSITIES

Condensation of the introduction to an address by Sir Walter Langdon-Brown before the Royal College of Physicians of Ireland and published in the Irish Journal of Medical Science, September 1940.

When barbarian waves of Germanic tribes and hordes from the Russian steppes threatened the last civilization as they are menacing this, it tottered, crumbled and fell like a child's sand castle before the incoming tide. Amid the shifting sands two outposts of that civilization still stood as if founded on the rock, Ravenna and Constantinople. From those two centers a new civilization began slowly to radiate. Ravenna helped to humanize the Goths, while Constantinople was the great repository of ancient learning. Considering the difficulties of transport, an astonishing thing about the Middle Ages is the degree of mobility displayed by those thirsting for the scant opportunities of acquiring any kind of education. The wandering scholars flocked hither and thither according as the reputation of some teacher waxed or waned. Where the man was, there was the school. The word universitas originally signified a guild formed for self protection either by the teachers or by the students. They needed these powers of combination, for they were strangers in a strange land. The feuds of town and gown were innate in the system, for the towns hated the students and yet were dependent on the money they brought. The universities claimed extraterritorial rights and privileges and gradu-

ally extended jurisdiction over the town. Here were inevitable sources of conflict. At this stage the university was an intangible affair, a thing of the spirit.

Even today in some respects at Oxford and Cambridge, the university itself is intangible. What would happen if a stranger arriving at Cambridge station were to tell a taxi driver to drive him to the university? As well might you arrive at Euston and ask to be driven to the British Constitution. How much more intangible was a university when it had no buildings and no endowments, when it was just the guilds of masters and pupils free to wander off if insulted by the townsfolk? This placed a powerful weapon in their hands; they could close down and journey to a more hospitable city with no more than their knapsacks, leaving financial disaster behind them. This weapon was repeatedly used with serious consequences until 1499, when King Louis XII and his parlia-

ment forbade the cessation of the University of Paris and won the day.

Paris and Bologna were the two most ancient universities. When the earliest universities arose, Germany was too far behind the rest of Europe in culture and civilization for the simultaneous development of a university. The first to be founded was Prague. In one day Prague was forsaken by the vast horde of German students who had been attracted there by policy of the Bohemian sovereign. Teuton and Czech could not live together in the same schools. It has been asserted this was the starting point of that long enmity between Catholic and Teuton which has culminated in a conflagration today. When the University of Berlin was subsequently founded, its charter declared that it should be unattached to any creed or school of thought. However, at present the head of its medical school is a Nazi official who is even medically qualified.

DO YOU KNOW WHAT PHYSICIAN—

1. Is known as the father of anatomy?
2. Later became a foremost comedian on the stage?
3. Was the greatest anatomist of his time but yet failed in his examination in anatomy to be marked "excellent"? (The answers are on page 18)

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

Course on "Treatment of Patients as Persons"

The freshman class at Harvard Medical School, Boston, had an unusual introduction to the study of medicine this fall when at one of their first lectures Dr. Charles S. Burwell, dean and research professor of clinical medicine, presented to the class a case of mitral stenosis with thyrotoxicosis and failure, complicated by social and personal problems, anemia and other complexities. The lesson in this demonstration was that physicians should have more insight into the understanding of such cases than the factual knowledge that they gain in school. These clinics for freshmen will be continued by Dr. L. J. Henderson and others as a voluntary course on "The Study and Treatment of Patients as Persons." Harvard is thus meeting a need recognized by the late Dr. Francis W. Peabody, formerly professor of medicine at Harvard, in an address before the medical students and published in *THE JOURNAL*, March 19, 1927, page 877.

Pennsylvania Seniors Returned Early

In consideration of the national defense program, the senior students at the University of Pennsylvania School of Medicine, Philadelphia, came back to their classes three weeks earlier this fall in order to complete the course on or before May 1. The freshman class at Pennsylvania is the largest in many years, comprising 129 students, representing seventy different colleges. The freshman class has been the first to adopt the newly constituted honor system under the control of the Student Board of Ethical Relations. The other classes have not yet voted on the system.

Expansion of University of Texas School of Medicine

The great expansion program which the medical branch of the University of Texas is undergoing is outlined by the president of the university, Horace Price Rainey, Ph.D., at the opening of the school of medicine in Galveston, October 1. Dr. Rainey's address was broadcast throughout Texas. Every department in the medical college is adding new members to staff and new courses are being made available, including courses in cardiology, biophysics, cell physiology, bacteriology, advanced anatomy and pharmacology. The research program also is being expanded. Plans are now complete for a new hospital building. The summer session of the quarter system at the school which was inaugurated last summer in order to assist in the country's defense program, proved highly successful. The students generally favor this plan, which allows them to go to school through the summer and thus graduate one year earlier.

First Assembly at Cornell

The largest enrolment in the history of Cornell University Medical College, New York, a total of 375 students, it is reported, assembled for the first time September 16 and were addressed by Dr. Samuel Levine, professor of pediatrics. Dr. Levine stated according to the *New York Times*, that the doctor must study not only the technic of healing if he is to take the leadership in the health program but also such social factors as nutrition, clothing, housing, etc.

ily income, educational and employment conditions; such preparation, he declared, "is either lacking or wholly inadequate in present-day medical education." The assistant dean, Dayton J. Edwards, Ph.D., awarded the following prizes: Walter F. Riker, a senior, first prize under the William Mecklenburg Polk Award for efficiency in research. John Langdon Norris, a junior, second prize.

Five scholarships amounting to \$700 each, established under the will of Dr. John Alfred Heim of the class of 1905, were awarded to Leyland E. Stevens, Henry Tesluk, Bruce M. Esplin, Morris O. Locks and William T. Mosenenthal.

Other scholarships were awarded to John B. Pfeiffer, Franklin Robinson, Francis S. Greenspan, Roy C. Swan Jr., Rosemary V. Gorman, Cedric C. Jimerson, Richard E. Kobilak, John H. Stover Jr. and George G. Reader.

The present first year class of 84 students at Cornell was selected from 1,070 applicants representing one hundred and eighty-five different institutions.

Michigan Awards the Sternberg Medal

At a special convocation of the University of Michigan Medical School, Ann Arbor, during the second triennial medical alumni reunion, the honorary degree of master of science was awarded to Dr. Warren T. Vaughan of Richmond, Va., and the Sternberg Memorial Medal was awarded to Dr. Cris J. Zarafonitis of Grand Rapids. Dr. Zarafonitis graduated from the medical school last June and is now an intern in the Boston City Hospital. The Sternberg medal was established by the University of Michigan Medical School in 1921 in honor of the late Dr. George M. Sternberg, a widely known bacteriologist and formerly surgeon general of the U. S. Army. The medal is awarded annually to the student who has the best record in the subject of preventive medicine. Dr. Vaughan is the son of the late Dr. Victor C. Vaughan, who was dean of the University of Michigan Medical School from 1891 to 1921.

Jefferson

Jefferson Medical College of Philadelphia opened its one hundred and seventeenth annual session September 17 with a lecture by Dr. Martin E. Rehfuss, professor of clinical medicine, on "The Medical Student of Today." The seventeenth dean of the college, Dr. William H. Perkins, was presented, and the announcement was made of his appointment also as professor of preventive medicine. The freshman class comprises 141 students, all of whom had received a bachelor's degree after four years of college work in one of sixty-six different institutions. The student body geographically represents twenty-nine states and two insular possessions.

Tennessee Chapter of A. O. A.

The Beta chapter of Tennessee of Alpha Omega Alpha national honorary medical society was installed at the University of Tennessee College of Medicine, Memphis, October 24. Orren W. Hyman, Ph.D., dean of the college of medicine, presided over the ceremony and accepted the chapter into the school. The honor was conferred by Dr. Walter L. Biering, of Iowa, a former president of the American Medical Association and now national president of Alpha Omega Alpha. The ceremony was attended by many guests, including the mayor of the city of Memphis, members of the board of trustees of the University of Tennessee and representatives of a number of other universities and colleges of medicine.

The certificates and keys were presented to the initiates by the national secretary of Alpha Omega Alpha, and responses were made by James D. Hoskins, LL.D., president of the University of Tennessee, Dr. Frank L. Roberts of the faculty of medicine and Dr. James B. Stanford. The charge to the new chapter was delivered by Dr. Waller S. Leathers, dean of Vanderbilt University School of Medicine. The student initiates were Edwin W. Couch, James N. Etteldorf, Noble O. Fowler Jr., Mary I. Griffith, Jim G. Hendrick, Milton M. Liebeskind, Russell H. Patterson Jr., Mary E. Plummer, William E. Sheffield and Ellison F. White Jr. The faculty initiates were Dr. Lathan A. Crandall Jr., professor of physiology; Dr. Lemuel W. Diggs, associate professor of medicine; Dr. Raphael E. Semmes, professor of neurosurgery, and Dr. James S. Speed, professor of orthopedic surgery.

Columbia

At the opening exercises of Columbia University College of Physicians and Surgeons, New York, September 24, Nicholas Murray Butler, Ph.D., president of Columbia University, gave the address of welcome and Dr. Harry S. Mustard, director of the DeLamar Institute of Public Health, gave an address on "The Nation's Health." The freshman class at Columbia comprises 125 students from thirty different states. One hundred and three students received scholarship aid for the current year, totaling more than \$37,000. Twenty of these scholarships were to out of town students to cover living expenses at Bard Hall, the medical student dormitory.

The Smith-Reed-Russell Society at George Washington University

This society at George Washington University School of Medicine, Washington, D. C., is named in honor of Dr. Theobald Smith, Major Walter Reed and Brig. General Frederick F. Russell, M. R. C., all former professors of bacteriology at this medical school. The organization has planned a series of monthly lectures, the first of which was delivered at the school of medicine, October 18, by Dr. Walter B. Cannon, professor of physiology, Harvard Medical School, Boston, on "The Effects of Emotions on the Body." The second address of the series was presented, November 5, by Dr. Esmond R. Long of the Henry Phipps Institute, University of Pennsylvania, Philadelphia, on "The Control of Tuberculosis as a Public Health Problem."

The newly elected officers of the Smith-Reed-Russell Society are Gilbert I. Anderson '42, president; Leo H. Siegel '43, vice president, and Sally L. Steele '43, secretary.

Lecture on History of Medicine at Tulane

The History of Medicine Society at Tulane University of Louisiana School of Medicine, New Orleans, is sponsoring a series of lectures to be held throughout the year, the first of which was delivered November 7 at Hutchinson Memorial Hall by Dr. Willard R. Wirth, associate in charge of the cardiac station at Touro Infirmary, on "The History of Cardiology." In December Dr. Conrad G. Collins, associate professor of gynecology and obstetrics, will speak on the history of childbed fever; in January Dr. Ambrose H. Storck, assistant professor of surgery, will speak on the army surgeon, and in February Dr. Julius Lane Wilson, associate professor of medicine, will speak on the history of tuberculosis. The public is invited to these lectures.

The Mann Lectureship at Indiana

Invitations were issued by the faculty of the Indiana University School of Medicine, Indianapolis, to attend the first lecture of the Frank C. Mann Lectureship, November 18, in applied physiology, supported by the Phi Beta Pi fraternity of Indiana University. The speaker was Dr. Frank C. Mann, Rochester, Minn., professor of pathology and experimental physiology and surgery, University of Minnesota Graduate School, and his subject was "The Circulation of the Liver." Dr. Mann was the author also of the leading article in THE JOURNAL, November 8 entitled "The Liver and Medical Progress."

West Virginia

The annual Phi Beta Pi lecture at West Virginia University School of Medicine, Morgantown, was delivered on April 17 by Dr. Howard T. Phillips of Wheeling on the subject of cutaneous diseases. The lecture was attended by medical students, premedical students and faculty. George S. Appleby '41 and Walter J. Glenn Jr. '41 served on the student executive committee for the occasion.

Illinois

The University of Illinois College of Medicine chapter of Alpha Omega Alpha national honorary medical society in Chicago announces the election to membership of the following members of the junior class: Charles E. Klontz Jr., Leonard Stone, Doris Clare Grosskreutz, George Bernard Golinkin Jr., Seymour Robert Cohen and Walter Kenneth Robinson.

Prizes Awarded at Jefferson

The following prizes, among others, were awarded by Jefferson Medical College of Philadelphia at the commencement June 6:

Laryngology Prize. By Professor Clerf, \$25 for general excellence in laryngology and bronchoscopy, to Frederick Alexander Robinson Jr., with Honorable Mention of Charles Nicholas Burns.

Neurology Prize. By Professor Alpers, \$25 for the best examination in neurology, to John U. Fehr.

Psychiatry Prize. By Clinical Professor Keyes, \$25 for the best examination in psychiatry, to Frederick Alexander Robinson Jr., with Honorable Mention of Hubert Horace Washburn.

Orthopedic Surgery Prize. By Professor Martin, \$25 for general excellence in orthopedic surgery, to Joseph Benjamin Crawford, with Honorable Mention of Frederick Balthas Wagner Jr.

Therapeutics Prize. A gold medal for the best examination in therapeutics, to Earl William Schafer Jr., with Honorable Mention of Joseph Benjamin Crawford.

The Pascal Brooke Bland Memorial Prize of \$25, given by Mrs. J. Hamilton Coulter in memory of her father, to the senior student who has shown the greatest aptitude and excellence in practical obstetrics, the student to be chosen by the professor of obstetrics and the money to be used exclusively for the purchase of medical books, the choice of which is to be left to the discretion of the student who receives the award, and the purchase of which is to be made through the librarian of the college, to Frederick Balthas Wagner Jr.

W. B. Saunders Company Prize. Seventy-five dollars' worth of their medical publications to the student who passes the best general examination at the end of the senior year, to Joseph Benjamin Crawford.

William Potter Memorial Prize. The income from a bequest of Mrs. Adaline Potter Wear, not exceeding \$250, offered to encourage excellence in the clinical branches of medicine and awarded to that graduate attaining the highest general average in the final two years of the medical course, to Frederick Balthas Wagner Jr.

Alumni Prize. By the alumni association, a medal for the best general average gained in the examinations for the entire curriculum, to Frederick Balthas Wagner Jr.

Physiology Prize. A gold medal awarded by bequest of Dr. Francis W. Shain for the best essay, or the best examination, on a subject pertaining to physiology (open to undergraduates of the second year), to Warren Reichert Lang '43, with Honorable Mention of Frank Clark '43.

Anatomy Prize. A gold medal, awarded on the completion of the sophomore year, to the student who has the highest grade in the anatomic subjects of the freshman and sophomore years, to Warren Reichert Lang '43, with Honorable Mention of Henry Harr Alderfer '43 and Paul Aloysious Ladden '43.

D. Appleton-Century Company Prize. Fifty dollars' worth of their medical publications to the student who passes the best general examination at the end of the junior year, to Paul Kram Perilstein '42.

Schaeffer Anatomic League Prize. A gold medal awarded to Professor Schaeffer to the member of the league presenting the best thesis in the science of anatomy, including embryology, histology and comparative anatomy, to William Henry White III '43, with Honorable Mention of Rhinard DeLancey Parry '41.

"DO YOU KNOW WHAT PHYSICIAN"

Following are answers to the questions appearing on page 1828:

1. Vesalius (1514-1564), who was the first to put dissection on a scientific basis. Vesalius, who was a student of Galen, drifted away from the traditions and superstitions of the time. Although retaining Galen's theory of separate venous and arterial circulations Vesalius described the internal anatomy of the heart in a way which anticipated more recent work in this line. After years of study and teaching at Padua he published his great work "De Fabrica Humani Corporis," which instituted a new era in the history of the physician. Vesalius, according to Bishop and Neilson, suffered the usual contempt and abuse for his radical departure. He retorted by destroying his available manuscripts, left Padua and deserted anatomy. A pretext for getting rid of this skillful anatomist, who was regarded dangerous by the Inquisition, was found in accusing him of having opened the body of a living man. He was sent to the Holy Land on a pilgrimage of penitence, and on his return journey he perished on the island of Zante, after having been shipwrecked.

2. Charles Wyndham (1841-1919). Sir Charles was born in Liverpool, the son of a physician. He qualified in medicine at the Royal College of Surgeons and the Society of Apothecaries and also graduated M.D. at Giessen by examination. He served as a surgeon in the federal army in the American Civil War and at times during that period appeared on the New York stage. He returned to England in 1865 and gained foremost place as a comedian. King Edward in 1900 conferred on him the honor of knighthood.

3. Dr. Jacob Henle (1809-1885), who graduated in medicine from the University of Bonn in 1832. In 1840 he became professor of anatomy and physiology at the University of Zurich, Switzerland, and from 1844 to 1852 he was professor of anatomy at the University of Heidelberg. His final examinations in anatomy at Bonn were given by Professor Schlemm, who gave him the mark "Good." Henle wrote to his father about this, expressing his keen disappointment and surprise. Henle's contributions to medical science were epochal. Garrison said that his histologic discoveries take rank with the anatomic discoveries of Vesalius. His name is found on the following parts of the body: trachoma glands of Henle, Henle's membrane (the lamina bursalis), Henle's fibrous layer, Henle's stratum nerveum, Henle's warts, Henle's layer (of the hair follicle), Henle's spine, Henle's ligament, Henle's fenestrated membrane, Henle's ampulla, the canal of Henle (the portion of the uriniferous tubule), Henle's cells, Henle's fibrin, Henle's internal cremaster, Henle's sphincter and Henle's loop, which he covered by injection. His greatest work, "Cernel Anatomy," was published in 1841 while he was at 310 in Zurich. During his years at Heidelberg time completed his main contribution to pathology, "book of Rational Pathology." During his years at tingen he produced his monumental work "doctor of Systematic Anatomy," which was followed by an Atlas a few years later, in which the excellent illustrations were reproductions of his own drawings.

Book Notices

Fractures and Other Bone and Joint Injuries. By R. Watson-Jones, B.Sc., M.Ch. Orth., F.R.C.S., *Civilian Consultant in Orthopedic Surgery of the Royal Air Force.* Second edition. Cloth. Price, \$13.50. Pp. 724, with 1,040 illustrations. Baltimore: William Wood & Company, 1941.

Following so quickly on the first appearance of Watson-Jones's book on "Fractures and Other Bone and Joint Injuries" (Baltimore, Williams and Wilkins Company, 1940), this edition offers few changes. In part I, chapter x, on the open and infected fractures of war wounds, there is added a short but excellent discussion on the limitations of antiseptic therapy, and we note with satisfaction that he considers antiseptics both useless and painful if applied to a wound day after day. There is also added to this chapter a short discussion on first aid (Thomas splint) and treatment of primary shock, wound shock and hemorrhage. Then there is also the distinction of wound treatment within the first twenty-four hours and that later than that, which seems to be a useful addition. Chemotherapy has found a short discussion on the action and complications of the sulfonamide derivatives and there is a short but practical paragraph on emergency amputations. The chapters that follow have remained essentially unchanged, with minor additions such as the use of a sliding bed with balanced traction in fracture of the femur (chapter xxxix) and a slight reclassification of the avulsions of the epiphysis of the tibial tubercle (chapter xxx). The work on the whole goes far beyond the usual territory covered in books on fractures and dislocations by including all traumatic situations, sprains and muscular injuries. Its principal virtue is the extreme thoroughness with which this field is covered in all details. The presentation is superb, the illustrations are excellent, the material is complete, the roentgenograms are of the best quality. All in all, it is a book of almost overwhelming thoroughness and practical presentation, attractively and artistically edited.

Hernia. By Alfred H. Inson, B.A., M.D., Consulting Surgeon, Long Beach Hospital, Brooklyn. In Three Sections: *Historical Evolution of Hernial Surgery; Technical; Medico-Legal Aspects.* Cloth. Price, \$15. Pp. 1,325, with 355 illustrations by Alfred Feinberg, Instructor of Medical Illustration, Dept. of Pathology, College of Physicians and Surgeons, New York. Philadelphia: Blakiston Company, 1941.

The text is divided into three sections. Section 1 consists of a chronological history of hernia, dealing principally with the maltreatment of inguinal hernia through the ages. The barbaric practices of the early surgeons are appalling and the variations in herniorrhaphy technic up to the latter part of the nineteenth century are shown to be principally variations in the method of mutilation. The author quotes extensively from early documents and, while the context sometimes wanders from the subject of hernia, it is an excellent historical review and very interesting reading.

Section 2 not only deals with current methods of herniorrhaphy but thoroughly covers the entire scope of the hernial problem as it is understood today. Citations from the literature are multiple and will serve to make this section invaluable as a reference book. This section is divided into a number of parts. Part 1 is a discussion of incidence and biometrics including age, race, occupation and heredity. Multiple tables serve to illustrate further these points. Such factors as the incidence of recurrence, traumatic hernias, complications and associated anomalies are also presented. An encyclopedic classification of hernias according to etiology, morphology, sac contents and clinical terminology is outlined that omits nothing. Next in this section is a presentation of the anatomy of the various hernial sacs. This portion deals with morphology, congenital defects and complications in a thorough manner. The author is to be highly commended for not simply reprinting the subject matter from the textbooks. He not only presents the standard descriptions but has condensed the recent additions to the anatomic knowledge. It is apparent from reading this section that the study of the hernial regions is not a static subject and that surgeons who base their repairs on nineteenth century knowledge are certainly in error. Part 2 deals with the varie-

ties, etiology, constituents, signs, symptoms, diagnosis and differential diagnosis of inguinal hernias. There is some repetition of previously presented subject matter, but on the whole it makes for clarity. Part 3 is concerned with the nonoperative treatment of inguinal hernias, including prophylaxis, palliation, the truss and the injection treatment. The preoperative preparation of the patient is a presentation of sound general surgical principles. Part 4 deals with the indications, contraindications and the various operations for reducible inguinal hernias. The many standard operations are presented. For each the objective is stated and followed by a description of the technic. The more popular operations are accompanied by adequate illustrations. Part 5 treats the subject of femoral hernia from definition to the various operations in the same thorough manner in which inguinal hernia is presented. Part 6 discusses the preoperative and postoperative complications of inguinal and femoral hernias and their treatment. The remaining parts of this section deal with umbilical, ventral, incisional and other less common hernias in a degree commensurate with their frequency. Again the more common operations are adequately illustrated.

Section 3 discusses the highly important subject of compensable hernia with its varied medicolegal aspects. The workmen's compensation laws in the forty-eight states and in foreign countries are presented.

This excellent textbook, encyclopedic in its scope, fills a definite need in the confusing and complex subject of hernia. It is exceptionally well written in a lucid style, well illustrated and unconditionally recommended to all who are interested in the subject of hernia.

Chemical Analysis: A Series of Monographs on Analytical Chemistry and Its Applications. Editorial Board: Beverly L. Clarke, J. M. Kolthoff, and Hobart H. Willard. Volume I: *The Analytical Chemistry of Industrial Poisons, Hazards and Solvents.* By Morris B. Jacobs, Ph.D. Cloth. Price, \$7. Pp. 661, with 110 illustrations. New York: Interscience Publishers, Inc., 1941.

This volume introduces the first of a series of monographs on analytic chemistry and its applications. The rapidly expanding literature on industrial hygiene attests the growing need for a compilation such as the present book; a collection into one volume of information about the numerous hazards and poisons with which the industrial hygiene chemist is concerned and the methods developed for their detection, sampling and quantitative determination. The scope of the book is indicated by a survey of the numerous chapters, which include industrial hygiene and industrial poisons, sampling, measurement of gas volume and quantity, absorbers and absorbents, the chemical and microscopic estimation of dust and silica, dangerous metals, the common poisonous compounds of sulfur, phosphorus, nitrogen and halogens, carbon monoxide, carbon dioxide, hydrocyanic acid and cyanogen, combustible solvent vapors, paraffin and unsaturated hydrocarbons, benzene and the aromatic hydrocarbons, halogenated hydrocarbons, alcohols, glycols, alcohol-ethers and ethers, acids, esters, aldehydes and ketones, phenolic compounds, aniline and derivatives, and chemical warfare agents. The numerous references to the original literature and the explanatory material given throughout the text make the volume a concise reference textbook as well as a convenient laboratory manual. A number of useful tables have been placed in the appendix. The author, well qualified by virtue of long contact with this field of chemistry, has adequately surveyed the tremendously large field of industrial hygiene and has presented in a clear manner a wealth of information useful both to the chemist and to organizations and individuals concerned with industrial hazards prevention.

The Occurrence and Prevention of Occupational Diseases Among Women, 1935 to 1938. By Margaret T. Mettert. United States Department of Labor, Women's Bureau. Bulletin of the Women's Bureau, No. 181. Paper. Price, 10 cents. Pp. 46, with 3 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

Nine state agencies furnished information for this report on the number of women injured by occupational disease—Connecticut, Illinois, Massachusetts, Michigan, Minnesota, Missouri, New York, Ohio and Wisconsin. The study included dry cleaning and nursing and the manufacture of pottery, asbestos, shoes and wood heels. Disabilities of women usually were of a tem-

porary nature. However, in one of the four states giving this type of information 12 of 63 women reported in 1938 suffered injury of a permanent character, and in two states fatalities were reported. Dermatoses were the most common type of disease reported of men and women in each state and comprised a higher percentage of the women's total. Dermatoses were followed by disability from repetitive motion, lead poisoning, volatile solvent poisoning, chrome ulceration, respiratory diseases and contagious diseases among nurses, teachers, household employees and hospital attendants. In all states the percentage of women disabled by occupational disease is much greater than the percentage they form of the total injured by other causes. In the various reporting states from 52 to 70 per cent of the women with industrial disease were less than 30 years old, though roughly half the employed women in each state were in such an age group. A marked difference existed between men and women in the proportion of those reported less than 20 years, attributable largely to the fact that youth characterizes employed females more generally than employed males. The evidence points to the need of special efforts toward prevention of disease among young employees. The study included evaluation of exposure to toxics, showing no variation from the already recognized hazards.

A Short History of Psychiatric Achievement with a Forecast for the Future. By Nolan D. C. Lewis, M.D., Professor of Psychiatry, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, \$3. Pp. 275. New York: W. W. Norton & Company, Inc., 1941.

The content of this book made up the Thomas W. Salmon Memorial Lectures. The book traces the beginnings of modern psychiatry through the Middle Ages and proceeds to modern advances such as those by Pavlov, Freud and his various offshoots and brings us at last into the psychosomatic point of view. The conclusion, which deals with prospects for future achievements, is stimulating to all who are concerned with research in psychiatry. The author tabulates the following main trends of such research:

- (a) The investigation of brain potentials and conduction phenomena in the central nervous system.
- (b) A search for detailed pathologic changes in the brain and other organs.
- (c) The physical and chemical variations in the blood, cerebrospinal fluid and other constituents of the body.
- (d) A study of the chemical equilibrium of the body.
- (e) The precise nature of the instinctive drives and urges.
- (f) The delineation of the elements entering the organization of personality.
- (g) The various patterns of personality reaction, including the disorders and the significance of the human environment in the home, the school, and in economic and other social adjustments.
- (h) The search for any medical and psychologic resources that could be utilized for therapeutic adjustments.

He finds a trend toward an American school of mental hygiene and psychiatry. Psychiatry has passed through the theological and metaphysical stages and has effected a closer affiliation of the whole temper of modern science.

Until the Doctor Comes. By James A. Dolce, M.D., Division of Sanitary Reports and Statistics, Federal Security Agency, United States Public Health Service. Miscellaneous Publication No. 21. Paper. Price, 10 cents. Pp. 60, with 16 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

This simple pamphlet can be purchased for a nominal sum from the Superintendent of Documents in Washington, D. C. It represents a straightforward, brief statement on first aid suitable for every home. It makes no attempt at involved medical treatment but mentions merely the simple measures that have had the test of time. Although surgeons are inclined to discount the use of tincture of iodine on wounds, this type of treatment is still supported by this book on first aid. Especially important is the simple advice regarding burns: 1. Do not apply ointments, grease or oils of any kind. 2. Never apply iodine to a burn.

The Keys of the Kingdom. By A. J. Cronin. Cloth. Price, \$2.50. Pp. 344. Boston: Little, Brown & Company, 1941.

Although educated as a physician, a contributor to medical research and a former professor of medicine, Dr. Cronin is best known now as a novelist of distinction. More particularly he is the trained craftsman. Thus "The Keys of the Kingdom," which has to do far more with the priesthood than with the

medical profession, exhibits a beautiful performance of novelist's art. It is well written and has sufficient dramatic climaxes and enough of human interest to place it promptly the best seller class. It was the choice of the Book of the Month Club for August.

The Therapeutics of Internal Diseases. Supervising Editor: G. Blumer, M.A., M.D., David P. Smith Clinical Professor of Medicine, Yale University School of Medicine, New Haven. Associate Editor: Albert J. Sullivan, M.D., Adjunct Clinical Professor of Medicine, Georgetown and Georgetown Medical Schools, Washington, D. C. Vols. IV and V. Cloth. Price, \$50 per set of 5 volumes. Pp. 791, illustrations; 765, with 27 illustrations. New York & London: Appleton-Century Company, Incorporated, 1941.

These are the concluding volumes in a new system of therapeutics of internal disease. They cover such topics as endocrine glands, the vitamins and allergy, which are, of course, centers of medical interest at this time. Since the contributors are men of repute in the subjects they discuss, the material must be considered adequate to the time of its preparation. There must be recognized that already the advance in some of the fields is considerable if only the last three to six months are considered. Nevertheless the quality and scope of this work make it exceedingly practical as an office and hospital reference, particularly when the physician is confronted with innumerable situations when something must be done and done promptly to meet a medical condition. Thus one finds in the article on hypertension only the most casual reference to recent studies with extracts of kidney.

Healthful Living. By Harold S. Diehl, M.A., M.D., Sc.D., Professor of Preventive Medicine and Public Health, University of Minnesota, Minneapolis. With a foreword by Morris Fishbein, M.D., editor, *Journal of the American Medical Association*. Whittlesey House Health Series. Morris Fishbein, M.D., editor. New revised edition. Cloth. Price, \$2.50. Pp. 499, with 61 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1941.

This is a new revised edition of a book that has had a large sale as a textbook in high schools and colleges as well as to the general public. The volume has had several reprintings. The new edition provides new references to up-to-date literature and up-to-date tables of new data, blanks for personal health records and new material dealing particularly with mental health and care of the aged. The book has had almost universal commendation and is undoubtedly one of the best books on personal hygiene available.

Hypophysäre Krankheitsbilder. Von Professor Dr. Wilhelm Faltl. Erweiterte Sonderdruck aus "Wiener Archiv für Innere Medizin," Band 33/34. Paper. Price, 5 marks. Pp. 56, with 5 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1941.

This small monograph consists of ten parts on diseases of the pituitary gland. These are: development, physiology and location of the hypophysis; pituitary cachexia; sclerosis of the endocrine glands; acromegaly and gigantism; Cushing's syndrome, diabetes insipidus and obesity. The booklet contains nothing new. All of the discussion and text material can be found in American literature. This contribution is not recommended.

The Second Yearbook of Research and Statistical Methodology: Book Reviews. Edited by Oscar Krisen Buros. Cloth. Price, \$5. Pp. 358. Highland Park, New Jersey: Gryphon Press, 1941.

This is a compilation of quotations from reviews of books and pamphlets on statistical methods. The excerpts from the reviews are taken from a wide range of journals, including some in the fields of medicine and health and hygiene. Naturally some of the reviews are much more informative than others. However, a pretty good idea of the contents and value of most of the books can be obtained from the selections given.

Man Without Uniform. By Willy Corsari. Cloth. Price, \$2.35. 358. New York: Greenberg, Publisher, 1941.

This is a typical continental scientific novel. It is the life of an investigator in the field of cancer who finds even such a love of research as this cannot shut him out of life and the world of women. Eventually he must state his final choice and he chooses, of course, devotion to doctoring the thousands of sufferers whom he can help. The theme of the book is that of Amsterdam. It seems to lack the qualities that make an absorbing novel.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BOXING GLOVES

To the Editor:—The selectees of our regiment have been boxing with Everlast EP-14 maroon boxing gloves. The dye has been coming off these gloves and is being rubbed into the bruises, abrasions and lacerations of the fighters. Could any serious dermatitis or infection of the blood or poisoning result from the chemicals in the dye? Could you tell us the formulas of the dyes used and their chemical properties? Would you consider these boxing gloves safe?

Peter Zanca, M.D., 1st Lieutenant, M. C.,
Fort Bragg, N. C.

ANSWER:—This response is made general since use of gloves of a brand other than the one mentioned possibly may lead to the same situation. The red, maroon and brown commonly observed in boxing gloves are not a matter of accident but represent the response to a demand for athletic commissions for colors that will not reveal the unsightliness of blood smears. Tanners for generations have been hard put to produce a soft unglazed red leather to meet this demand. Most such leather bleeds or cracks on contact with water or perspiration or on being rubbed. Boxing glove leather ordinarily represents pickled sheepskins which have been chrome tanned. Many types of pigments and dyes may be used in bringing about a maroon color, together with several adjuvant solutions such as sumac extract, animal oils, plasticizers and retanning agents. In some brown gloves the well known sensitizing dye paraphenylenediamine may be employed. The occurrence of bleeding or cracking in boxing gloves is undesirable but not serious. Some combination of the following red pigments and dyes is likely: crocein scarlet, hyperic salts, red iron oxide, chrome red, cadmium red, para red, helio red and lithol red. Usually more than one dye is applied. Theoretically certain of these coloring materials are harmful, as for example cadmium red, which represents sulfides of cadmium and selenium, and the para reds, which embody a content of paranitranilin, a well known source of dermatitis, but the prospect of practical and widespread harm from dyes in boxing gloves is negligible.

On occasion some one boxer might be made sensitive to or, if already sensitive, an allergic reaction may be precipitated by such material as paraphenylenediamine, chromium salts, sumac extract or paranitranilin, but this risk is subordinate to the potential dangers of bacterial action from oral and nasal organisms promiscuously smeared about the body in any bout.

Elimination of cracking or bleeding from red colors in boxing gloves constitutes a difficult task for the tanner, and possibly, there should be a willingness on the part of athletic commissions to approve of other colors, since the mere hiding of blood stains does not eliminate the insanitary features that may be entailed.

INGESTION OF METALLIC MERCURY

To the Editor:—What happens to one who swallows 27.2 Gm. of pure metallic mercury? The textbooks and the U. S. Pharmacopeia fail to mention the effect of ingestion of metallic mercury. I conclude from blue mass and mercury with chalk that there would be nothing but laxation. I should appreciate complete and authoritative information.

Heinrich Lamm, M.D., La Feria, Texas.

ANSWER:—When a single large dose of metallic mercury, such as 27.2 Gm., is swallowed it might produce transient discomfort as a result of its accelerated descent into the lower part of the esophagus and the stomach. According to the prevailing opinion it would pass through the stomach essentially unchanged. In the small intestine, in the presence of the alkaline contents and bile, a small amount would be converted to mercuric oxide and possibly sulfide. The effect of the mercuric would be threefold: (1) precipitation of protein either in intestinal contents or in the intestinal mucosa; (2) irritation of the intestinal mucosa with increased peristalsis and subse-

location; (3) absorption of the soluble mercuric ion combined with protein. The extent to which such actions take place would depend on the length of time the mercury remained in the intestine. The chances are that under ordinary conditions only a small and perhaps inconsequential amount would be absorbed. Laxation would undoubtedly occur, and the major proportion of the mercury would be excreted as metallic mercury and a small amount in combination with bile.

MAGNESIUM SULFATE AND CONVULSIONS

To the Editor:—A man received a severe blow on the head a number of years ago and lost consciousness. He was hospitalized, and examinations revealed inequality of the pupils, tubular vision, corneal hypesthesia on the side of the larger pupil, absent pharyngeal reflex, diminution in sensation of the left side of the face, loss of bone and air conduction on the left, tremors of the hands, hyperactive deep reflexes on the right, diminution to pain touch and vibration on the left. These diffuse findings, which were determined by recognized neurologists, were supplemented by three or four encephalograms done by leading neurologists, and these revealed definite dilatation of the ventricular system. Other laboratory work (Kahn and other tests) was negative. Shortly after the accident, the patient developed repeated attacks of unconsciousness, during which he sustained repeated fractures of the fingers, nose and zygoma and was repeatedly picked up in the street and hospitalized. Accompanying these attacks was an obvious change in the personality of the patient. He became irritable, impatient and bellicose, and he carried a "chip on his shoulder." Treatment consisting of phenytoin, 1½ grains (0.1 Gm.) every two hours, together with as much as 5 grains (0.32 Gm.) every three or four hours of phenobarbital alum, doesn't seem to affect the frequency of the attacks much. He has been hospitalized, and these massive doses of phenobarbital have been administered by hypodermic because it was believed that the patient was a "phony" and was not taking the medication, but the only effect it had on him was to increase his irritability. Other barbitol derivatives, chloral and bromides were also ineffective. Recently, because of the severity of the injuries sustained by the severe attacks of the traumatic epilepsy, I tried the intravenous injection of magnesium sulfate, 5 cc. of 25 per cent solution. This I give slowly about every other day. I find that this is more sedative than the phenobarbital, without producing any irritative phenomena. The patient professes that he also sleeps better and has fewer attacks. Outside of a slight fall in blood pressure and a diuretic effect, I haven't noticed any ill effects. Please advise me if any work in the past has revealed any danger from repeated intravenous injections of magnesium sulfate, and whether any one has ever tried it for epilepsy and with what results. Of course, I am not seeking a panacea.

M.D., New York.

ANSWER:—It is quite apparent that the blow on the head produced severe cerebral damage. This may have been localized or petechial hemorrhage or subdural hematoma. The underlying pathologic condition may be a posttraumatic softening. The encephalograms would suggest the latter. It is quite probable that sedatives will not control the resulting convulsions. Magnesium sulfate was used originally with the intention of dehydrating the brain. Then there is the additional effect of magnesium. As long as the injections are given slowly enough to avoid sclerosing the veins, there should be no harmful effect from repeated injections. The intravenous injections may be alternated with intramuscular injections. The patient should be given a dry diet, with a fluid restriction to the absolute minimum, 500 or 600 cc. daily. Peterman has recommended the injection of magnesium sulfate in the treatment of convulsions since 1925.

WOUNDS INFLICTED BY STING RAYS

To the Editor:—Wounds inflicted by sting rays are usually extremely painful and disabling. Will you kindly advise me whether any special studies of treatment of such wounds have been made and whether any particular treatment is reported to have given good results?

O. L. Chason, M.D., Mobile, Ala.

ANSWER:—From classical antiquity to the present day this question has been asked but until comparatively recent times not conclusively answered. Aristotle named several dangerous fishes and among them Trygon (the European sting ray). But down to the present it has been declared nonpoisonous. Thus the Cambridge Natural History (Fishes, vol. VII, 1904) states that "... except the mucus secreted by the gland cells of the skin, which may possess venomous properties, no special poison-forming glands in connection with the spines are at present known."

However, in 1905 Antonio Porta (*Anat. Anz.* 26:232) described a glandular structure in the tissues filling the lateral grooves on the under side of the spine of Trygon. His account abounds in errors—e. g. he stated that the spine is renewed every year—and seems to have been comparatively unnoticed.

In 1916 H. Muir Evans, of the Lowestoft Hospital, England, published (*Proc. Zool. Soc. London*, pt. 1, p. 431) a description of "The Poison Organ of the Sting-ray (*Trygon pastinaca*)."

In 1924 he published a general paper, "The Defensive Spines of Fishes . . . the Glandular Structure . . . with Observations on the Nature of Fish Venoms" (*Phil. Tr. Roy. Soc. London* 212:B:1).

By means of sections Evans found on the part of the tail where the spine commences a true glandular epithelium. This epithelium extends forward in each groove on either side of the bony ridge on the under side of the spine. The epithelial cells show signs of secretory activity, and the products are discharged toward the toothed margins of the spine.

Evans made no experiments on the poisonous nature of the spine and the products of the glandular tissue. However, he submitted that the acute pain, inflammation and paralysis are similar to the symptoms produced by the stings of other venomous fishes with which he experimented. He quoted various accounts of an attack by a sting ray resulting in almost instantaneous prostration with convulsions. The sloughing wounds give off a copious fetid discharge and separate, exposing the bone of the arm or the leg.

There are in the literature at least five recent accounts of attack by a sting ray which follow the pattern set out. Caullery (*Compt. rend. Acad. d. sc.* 192:1279, 1931) experimented on dogs by pricking them deeply with dried spines. All died with the symptoms which follow attack by a live ray.

Muir advised from practical experience that wounds made by the spines of any poisonous fish are best treated by injection into the wound of a 2 to 5 per cent solution of potassium permanganate. He had heard that a 1 per cent solution of gold chloride gives good results. Solution of formaldehyde has also been used. In an unpublished report it is stated that after an attack by a sting ray that seemed likely to result fatally, full strength solution of formaldehyde was injected. Probably, however, 5 per cent of commercial product would be strong enough.

FORMALDEHYDE

To the Editor:—This inquiry pertains to the answer given to the query entitled "Masks For Protection Against Formaldehyde Gas" (*The Journal*, June 7, 1941, page 2639). The following sentence is of interest to me: "It is rather rare, however, to obtain a toxic concentration of formaldehyde under ordinary practical conditions, in spite of the fact that the exact range of toxic concentration is not known at the present time." Am I to interpret this statement to mean that persons who might be working in the presence of formaldehyde gas are not apt to suffer ill effects when good ventilation exists and they are not wearing a protective mask? How does the commercial use of paraformaldehyde fit into the various comments made in the answer referred to? Finally, what are the risks of cutaneous irritation due to handling of articles moistened with 10 per cent formaldehyde?

M.D., Illinois.

ANSWER.—It is indeed curious that in spite of the widespread industrial use of formaldehyde and its products there is so little known, relatively, regarding its physiologic properties. It is true that bronchitis and other forms of mucous membrane irritations have long been suspected, but never actually proved, as due to exposure to formaldehyde. As far as can be determined, if good ventilation exists and if the concentration of formaldehyde does not exceed 0.025 mg. per liter or 20 parts per million (Ficklen) during the entire work period, the worker will not suffer any harmful effects even though he does not wear protective masks. Information is available that with good ventilation this concentration is hard to maintain for any length of time, under ordinary work conditions. However, special protective masks are advised when one is exposed to formaldehyde in cleaning out huge tanks where the ventilation is poor. It must not be forgotten that differences in susceptibility of the mucous membranes to formaldehyde exist also. Although there are no data readily available, it would seem as if the same facts would apply also to the commercial use of the polymerization product of formaldehyde, paraformaldehyde. Toxicologic works do not mention any significant toxic differences between formaldehyde and paraformaldehyde. As regards cutaneous injury, formaldehyde is a strong sensitizing agent. Five per cent is usually the upper limit of the concentration of formaldehyde employed to make patch tests of hypersensitive skins. So there is a definite risk of cutaneous irritations from articles moistened with 10 per cent formaldehyde. These irritations may vary from extensive vesicular dermatitides in more sensitive to dryness, thickness and fissuring of the skin in less sensitive individuals.

RATIO OF MASCULINE BIRTHS IN WARTIME

To the Editor:—Is the proportion of male births greater for a few years after a war of the magnitude of World War No. 1?

F. A. Neergaard, M.D., Harriman, Tenn.

ANSWER.—The proportion of male births to female was above its prewar level in every European belligerent power during the last years of World War I and for perhaps two or three years afterward. The proportion of male births increased also in many of the important European neutral countries, including Norway, Sweden, the Netherlands and (for the year 1920) Switzerland. There was an observable rise in Australia, but not in the United States or in New Zealand, among the non-European belligerents. The increase in the proportion of male births, where observed was of short duration. Such explanations

usually based on differential sex mortality before birth. It has been suggested, for example, that mobilization of an army, by removing a large proportion of the male population, increase the average interval between pregnancies and thereby improve the ability of the maternal organism to support the male fetus which normally suffers greater mortality hazards than the female. This has scant biologic foundation and would not explain the rise in neutral countries, however, or the absence of an increase in the number of masculine births in the United States during and after the last war. The hypothesis that malnutrition favors the male embryo is not supported by data on the sex ratio at birth during famines in India. A simple explanation that seems entirely adequate has not yet been offered.

TRACTION FOR FRACTURED FEMUR

To the Editor:—In treating fractured femurs with traction apparatus, does some angulation of the fragments at the fracture site occur when the patient moves, as in trying to get on a bed pan, even though many types of apparatus are made to adjust themselves so as to have the traction always in a straight line? This is one of the arguments that was given at the Cleveland convention by men demonstrating the use of the hanging cast in fractures of the humerus. Men here cannot see any other method but absolute immobilization of such fractures of the humerus. I would appreciate any information you may have to show that such angulation does occur.

Theodore P. Murphy, M.D., Montpelier, Vt.

ANSWER.—The many forms of traction apparatus used for fracture of the femur all have merit, but they are not "fool proof." Not only must care be taken to be certain traction is really working, but also some form of lateral splinting is often advisable to push the fragments over into proper alignment. The Thomas traction splint has been used for many years with generally satisfactory results. Other methods of traction, such as skeletal traction and the Russell countertraction method, also have produced satisfactory results. The use of the bed pan tends to disturb the relations of the fragments, but using the Bradford frame with an opening beneath the buttocks permits use of the pan without disturbing the position of the leg.

Angulation following a fracture of the femur certainly does not always occur and can be avoided or minimized through the proper use of traction and side splints. If angulation cannot be controlled properly, it may be better to open the fracture and apply a vitallium plate. If this form of internal fixation is used, external support by a cast is also necessary. Overlapping does not necessarily mean a poor functional result if the fragments are in correct alignment and there is no angulation.

Comparison cannot be readily made between the various methods of treatment of fractures of the humerus and those of the femur, as the latter is a weight bearing bone while the humerus is not.

While many objections to hanging casts for fractures of the humerus have been advanced, good results have been and are being obtained through this simple procedure. Apparently it is most effective in fractures of the upper half of the humerus.

PURPURA HEMORRHAGICA FROM ARSENICALS

To the Editor:—A white woman aged 18 received in the course of ten months twenty-six intravenous injections of neorsphenamine and eighteen injections of a bismuth compound given at weekly intervals in doses of 0.6 Gm. and 2 cc. respectively for preceptive syphilis. Prior to the last dose of neorsphenamine she noted large bruises on two areas of her body. She was given 0.6 Gm. of neorsphenamine intravenously. The following morning she awakened bleeding from the mouth, gums, pharynx and profusely from the uterus (the menses were due). Her hemoglobin was 13.6 Gm. per hundred cubic centimeters and the bleeding time seven hours. Bleeding from the mouth gradually subsided and the menses returned to a normal flow. Four days later her hemoglobin was down to 9 Gm. per hundred cubic centimeters and the bleeding time was twenty minutes. I assumed that this purpura was from the neorsphenamine. Does this contraindicate additional arsenical treatment? If so, should the required number of intravenous treatments be replaced by a bismuth compound?

M.D., Minnesota.

ANSWER.—This patient doubtless has a disturbance of the hemopoietic system as a result of the arsenical therapy. The "large bruises" can be considered as early evidence of it. Her blood should be checked from the standpoint of granulocytopenia and the platelet count may be found as low as 310. This is a serious reaction to the arsenicals and at this time it is unwise ever to give these patients further arsenical treatment. For the present it would be just as well to suspend the syphilitic therapy, for, after all, one is treating the patient for syphilis. A transfusion must be considered if the condition demands it. If there is any question, it is advisable to have consultation.

THE VALUE OF PHYSICAL THERAPY IN INTERNAL MEDICINE

GEORGE MORRIS PIERSOL, M D

PHILADELPHIA

It may be stated with little fear of contradiction that there is no field of therapeutics less understood and less frequently employed by internists than physical therapy. There are several reasons that account for this unfortunate state of affairs which has its inception in our medical schools. A survey of the curriculums of undergraduate as well as graduate medical courses reveals the fact that, if taught at all, but little time is devoted to the various aspects of physical therapy and that at best the courses available to students of medicine are inadequate and superficial. The average physician, therefore, approaches the practice of medicine knowing little about one of the oldest and most useful branches of therapeutics. Physicians, as a rule, because of their lack of understanding, evince little interest in acquiring a sound working knowledge of physical therapy. Furthermore, the proper application of physical therapeutic methods requires not only time but a certain amount of manual dexterity. Since physicians have been loath to give of the former or to acquire the latter, the field of physical therapy has been neglected by the medical profession.

Gradually the various procedures that are embraced in this form of therapeutics have been delegated to technicians who not only have acquired skill in carrying out such measures but have been allowed to usurp the actual prescribing and direction of this type of therapy. The lack of appreciation on the part of the medical profession of the value of physical therapy and its disinclination to devote the time and study necessary to master the basic principles which underlie it have been major factors in affording opportunity for cultists to develop and monopolize this field. The public has long been aware of the value of physical therapeutic methods. It is unfortunate that the profession should have turned a deaf ear to this popular demand, thereby allowing less orthodox and less scientifically trained groups to become aggressively active in a field which should be and should always have been under the control and domination of qualified physicians.

The first step toward correcting this situation is to revise our educational methods as far as physical therapy is concerned. Students of medicine, undergraduates and graduates, as well as interns and residents, should be taught that in the field of therapeutics in its broadest sense, physical methods occupy a recognized position of importance. To many the term "physical therapy"

conjugates up a picture of elaborate apparatus and expensive paraphernalia. Such a conception is both erroneous and discouraging. It should be emphasized that, basically, physical therapy is founded on procedures that are relatively easy, that are readily available and that require for their proper application not elaborate equipment but a thorough understanding of their underlying physiology and their proper uses and limitations.

In this discussion, no attempt will be made to deal with such highly technical subjects as electrotherapeutics and radiation therapy. Such procedures should not be so generally available, since their safe and proper application requires adequate special training. An effort will be made to emphasize those physical therapeutic procedures concerning which all physicians should have sufficient working knowledge to supervise and direct their use intelligently, even though they lack the personal skill to carry them out. This category embraces massage, exercise, the application of heat and hydrotherapy.

MASSAGE

Among the oldest, best known and most frequently employed forms of mechanotherapy is massage. In view of this, it is the more remarkable that physicians as a whole possess so little understanding of the effects of massage and the methods of application. Pemberton¹ emphasizes this in his statement "There is probably no other measure of equal known value in the entire armamentarium of medicine which is so inadequately understood and utilized by the profession as a whole." Since few physicians are capable of directing the proper application of the various technics of massage, in this country at least, the task is delegated to lay technicians who, for lack of expert guidance, more often than not decide on the form of massage to be used as well as the duration and frequency of its application. Responsibility for all forms of therapy is definitely the physicians'. It is as unjustifiable for them to shift that responsibility to a physical therapy technician, no matter how well trained, in the case of massage, as it would be for physicians to delegate the details of drug therapy to a druggist.

In spite of the work of Pemberton,² Coulter,³ Mennell⁴ and others who have studied with modern methods the physiologic effect of massage, much remains to be done to bring about a complete understanding of the basic principles of this subject. Pemberton and his associates have shown that even after vigorous massage there is no production of lactic acid in the muscles, and consequently the acidosis characteristic of exercise is not

ent. They were unable to demonstrate that massage brought about the loss of lactic acid and alkalosis that accompanies the application of external heat. They believe that the important effect of massage on the circulation is different from that induced by exercise or the local application of heat and is to be explained on the basis of the effect which even mild stroking has on the capillary bed, as demonstrated by Krogh.⁵ The dilatation that follows light pressure is transitory, but heavier pressure causes more extensive and persistent widening of the capillaries. Direct observation on the capillary circulation indicates that massage causes an increased rate of blood flow and changes in the vessel walls, followed by an increased interchange of substances between the blood and tissue cells and consequent improvement in metabolism.

The mechanical effect of massage on the return flow of the venous blood and lymph to the heart has long been recognized. This effect is especially obvious in the presence of edema that can be favorably influenced by even light centripetal stroking. The therapeutic application of this fact has been utilized in the treatment of local edema of traumatic origin but has not been taken advantage of in the management of edema due to general causes. Since by pressure fluids can be displaced from the subcutaneous tissues, it would seem that massage might play a useful role as an adjunct in the relief of edematous states.

It was shown by John K. Mitchell⁶ that massage increases the number of red blood cells and the amount of hemoglobin in the circulating blood. This effect was observed not only in health but in anemic states. These conclusions were confirmed by subsequent observers.

The effect of massage on the nervous system varies according to the type of massage employed, its intensity and duration. Properly applied massage may cause either a sedative or a stimulating effect.

It is generally believed that heavy massage is capable of reducing local deposits of fat. Clinical and experimental evidence show this to be a popular misconception. There are no scientific data to support the contention that massage ever removed collections of adipose tissue from various parts of the body. A similar misunderstanding exists in the minds of those who believe that massage will strengthen muscles. There is general agreement that massage does not increase muscular strength, which can be brought about only by active exercise.

Contrary to what might be expected, it has been shown that massage has little effect on general metabolism. Many observers have noted a definite increase in the output of urine. No disturbance of the acid-base equilibrium of the blood has been recorded, nor is the consumption of oxygen influenced by massage. After a careful review of the subject, Pemberton comes to the conclusion that "the cumulative effect which massage exercises on various metabolic processes probably lies in the mechanical influence on the circulation of the parts concerned."

The diseases in which massage is indicated are for the most part of a chronic nature, since the therapeutic effect of massage is brought about slowly as the result of repeated use over a long period of time. Therefore massage has a limited field of usefulness in acute conditions that run a short course. It has its greatest value in chronic states that involve long periods of inactivity which bring about atrophy of muscular tissue. Under

such circumstances massage helps to prevent further atrophy, aids in the absorption of exudates and toxic waste products and restores normal physiologic processes in the masses of muscle. When to these effects are added the influence of proper massage on the nervous system, it is easy to understand why massage has become an indispensable aid in arthritis and allied rheumatic conditions as well as in fibrositis and other muscular derangements. It is almost equally useful in long-continued convalescence, in functional nervous disorders and in asthenic states often included in the term "neurasthenia." The possible value of massage in certain secondary anemias has already been referred to. The helpful effect of suitable upward stroking on the venous return flow and in increasing the absorption of edematous fluid into the circulation suggests that in certain stages of chronic cardiac failure massage could be used to advantage to help restore circulatory equilibrium and relieve edema, a fact which has been generally overlooked. There are few medical conditions for which, at some time, massage has not been advocated, often with little or no sound basis. Like all forms of therapy, it has its definite indications as well as its contraindications with which internists should be thoroughly familiar.

EXERCISE

It is generally admitted that the proper kind and amount of physical exercise is essential for the maintenance of good health. In this country during the past fifty years the trend in exercise has been toward less formal gymnastics, more sport activities and a decided increase in the employment of corrective exercise.

Physicians should acquaint themselves with the indications for and the possibilities of the various types of exercise; they should know how and when to prescribe them and be willing to supervise their application. This is especially true of corrective exercise, a valuable form of physical therapy that is too much neglected. The physician is prone to think of exercise as a means of increasing muscular strength rather than as an aid in restoring normal function.

The mechanism of muscular contraction is still not entirely clear. Muscular work causes the expenditure of energy. How this energy has been produced has been a subject of much investigation. The fundamental work of Fletcher and Hopkins⁷ has shown that, when a muscle contracts, glycogen, which is present in muscles in large amounts, disappears, lactic acid accumulates and carbon dioxide is driven off. The reaction of the muscle then becomes less alkaline because of increasing amounts of carbonic acid and lactic acid. This series of chemical changes which bring about the liberation of energy which enables muscles to contract requires no oxygen. The whole process is referred to as the contractile phase of muscular contraction. The accumulation of lactic acid causes a cessation of muscular movement, and for further muscular effort additional changes must take place which are dependent on oxidation and are known as the recovery phase of muscular contraction. In this phase, in the presence of adequate oxygen, the lactic acid disappears, glycogen reaccumulates and the muscles return to a state of alkalinity. If muscular effort is to be continued, large amounts of oxygen must be available. It has been shown that an individual doing hard muscular work will require ten times more oxygen than is needed when he is at rest. This increased oxygen requirement is met by com-

persatory changes in the circulation and in respiration brought about by a greater volume of breathing and increased circulation of the blood. Therefore, during exercise there is an increased pulse rate, a larger output of blood, an elevated blood pressure and a more rapid respiratory rate. These vary with the rapidity, severity and duration of the muscular effort according to the degree of training of the person.

The surgeons, orthopedists and neurologists have taken advantage of the therapeutic value of exercise to a greater extent than have internists. Nevertheless, there are certain conditions that constantly come under the observation of physicians which can be greatly benefited by the employment of appropriate exercises. It has been frequently observed that the commonest defect noted among the people of this country is faulty posture with its resultant incorrect body mechanics. The far reaching, harmful effects of poor posture as well as its influence on various disease conditions and on the morale and psychology of patients is too well known to require elaboration. A better understanding on the part of physicians in general of the results of postural strain and faulty body mechanics, coupled with an intelligent knowledge of the therapeutic exercises necessary to overcome such conditions, would better enable them to restore the physical and mental well-being of many a patient, a task which today must too often be turned over to technicians or to those who have become the advocates of certain special schools of mechanotherapy.

Internists might well be more alive to the value of certain forms of exercise in the treatment of cardiac disease. Years ago, the Irish clinician Stokes advocated exercise, particularly mountain climbing, for certain types of heart disease. Later such exercises were put on a more systematic and scientific basis by Oertel. Today the Stokes-Oertel graduated hill-climbing exercises for selected cardiac patients are recognized as an effective form of therapy which, however, is largely overlooked by clinicians and rarely employed except in well regulated health resorts. Another form of exercise of undoubted value in many cardiac conditions was introduced by August and Theodore Schott of Nauheim. They developed resistance exercises, regulated movements that could be carried out by trained attendants with little exertion and no fatigue on the part of the patient. That all such exercises should be carefully controlled and immediately stopped on the appearance of any symptoms of cardiac fatigue such as dyspnea, palpitation, precordial distress or undue exhaustion is axiomatic. In the presence of decompensation, rest is obviously essential, but many cardiac patients are forced into states of invalidism because rest and the avoidance of all forms of exertion are insisted on unnecessarily.

There are few persons who cannot derive benefit from properly regulated and suitable voluntary free exercise. Careful judgment should be shown in prescribing exercises for middle aged and older persons, particularly those who are suffering from early and often symptomless cardiovascular disturbances. Serious harm, at times even death, has resulted from a physician casually telling such patients that they need exercise without specifically prescribing the character and the amount. The tragedies of the handball and tennis courts and the golf course bear eloquent testimony to this fact. Lack of time or interest are the chief reasons that prevent the busy practitioner from specifically prescribing suitable exercises. This difficulty may be overcome by having on hand printed instructions for a set

of simple exercises that may be given patients, with modifications and restrictions suited to their needs, or, as Coulter has suggested, by making available to such patients one of the useful handbooks on exercise that have been published under the direction of the Council on Physical Therapy of the American Medical Association.

EXTERNAL HEAT

One of the most valuable physical therapeutic measures available is the application of external heat, which may be general or local. Although the systemic use of external heat has been employed for many years, it is only recently that the value of the artificial production of an increase in bodily temperature or "fever therapy" has been fully appreciated. The fever produced is the result of creating by physical means a disproportion between heat production and heat dissipation. The production of artificial fever may be brought about by various methods; from such comparatively simple procedures as hot tub baths and hot packs to the most complicated forms of heat cabinets. Artificial fever therapy is a major procedure which should be carried out only by those thoroughly familiar with its various aspects and in suitable institutions. It would be inappropriate to consider here the technic of fever therapy. The procedure is obviously a heroic one, and patients who are subjected to it should be selected with the greatest care and, as Krusen⁸ has pointed out, should be conditioned both physically and psychologically for the ordeal of enduring prolonged high fever therapy. Although the possibilities of this form of therapy are great, it obviously has limited application. After a careful analysis of the literature, Krusen found that fever therapy had been employed for more than fifty diseases, in the majority of which it has proved of little value. It has been found of distinct advantage in syphilis, particularly in syphilis of the central nervous system. Gonorrhea and its complications, atrophic arthritis, undulant fever, rheumatic fever, intractable bronchial asthma and some forms of neuritis have shown a favorable response to this form of therapy. Most recently encouraging reports have come from the Mount Sinai group in New York of the results of fever therapy in subacute bacterial endocarditis when the treatment is fortified by chemotherapy and repeated blood transfusions.

The general application of heat is by no means limited to the production of prolonged artificial fever. It is much more often employed to bring about various degrees of sweating. To accomplish this, the various forms of cabinets used for fever therapy may be employed. The best known methods are the use of hot packs of various kinds, steam baths, hot room and cabinet baths. The heat, whether it is dry or moist, thus applied is maintained for only a short time, not more than thirty minutes even when free sweating is to be induced. Whatever rise in body temperature occurs is but slight and transient.

Popular faith in the ability of sweat baths to eliminate poisonous waste products and to reduce weight has given this form of therapy great vogue among the laity, which is too prone to indulge in it without medical supervision or approval. Devices for inducing sweats form an important part of all physical therapeutic establishments and are the basis for the Turkish bath.

It is unnecessary to dwell on the danger of this form of therapy when it is practiced to excess or unsupervised or by those whose physical condition contraindicates

8. Krusen, F. H.: *Physical Medicine*, Philadelphia, W. B. Saunders Company, 1941, p. 45.

cates its use. Patients become conscious of palpitation and a feeling of fullness and a throbbing in the peripheral vessels. Syncope may occur, especially in those who are sitting erect in cabinets; for that reason it is best to give such treatments with the subject recumbent. If sweating is profuse and prolonged, dehydration and hyperventilation bring about alkalosis. In many instances there is a decrease in the serum chlorides. The blood urea, uric acid and creatinine are little if at all affected; the same is true of the non-nitrogenous constituents of the blood. The loss of weight following prolonged sweating is rarely excessive, is of short duration and is due to dehydration. To offset the dehydration with its attendant loss of electrolytes, adequate amounts of water and in some instances sodium chloride should be administered during the sweat.

Diaphoresis brought on by the general application of heat is at times of value in selected cases of arthritis, fibrositis and allied conditions as an adjunct to other forms of therapy. As a method of promoting loss of weight, unless combined with exercise and dietetic restrictions, it is of little value. Formerly it was extensively employed in acute and chronic glomerular nephritis in which there was nitrogen retention and threatened renal toxemia. Since, as indicated, the application of external heat brings about loss of water and of sodium chloride without influencing to any noteworthy extent the nonprotein nitrogen of the blood, there is some question as to its value in impending uremia, and the use of sweats in renal diseases has lost much of its earlier favor.

LOCAL APPLICATION OF HEAT

The local application of heat constitutes one of the commonest procedures in medicine, readily available and frequently applicable. There are three well recognized methods by which heat is locally applied to the body: 1. Conduction, when it is applied by direct contact from a heated object such as a hot brick, a hot water bag or an electric pad. 2. Convection, when the heat is applied to the surface of the body from some external source such as heated lamps, coils or reflectors. 3. Conversion, in which heat is developed in the tissues of the body by reason of the resistance which they offer to the passage of a high frequency current (diathermy).

The physiologic effects of local applications of heat differ but little whether conductive, convective or conversive heat is used, with the exception that the former is least penetrating and the latter produces the greatest amount of penetration. When heat is locally applied, the blood vessels dilate, the rate of blood flow increases, as does the transfer of fluid from the blood to the tissue. This acceleration in blood flow interferes with local rise in temperature by distributing the heat throughout the body. Local heat tends to produce an alkalosis and to increase local metabolic activity and possibly phagocytosis.

The methods employed for applying heat locally are numerous and include devices that depend on heated air, chemical heat, electrically heated applicators, heated solids and semisolids such as mud and paraffin and water heated applicators.

The indications for the use of local heating are many and are essentially similar whether the heat used is of one kind or of another. Among the conditions for which local heat is recommended, again arthritis and rheumatic states come first. It has been used in many inflammatory conditions, especially pelvic, as well as in traumatic conditions and in peripheral vascular disease.

LIGHT

Closely allied to the therapeutic use of heat is that of light. In recent years there has been an ever increasing interest in the use of ultraviolet, visible and infra-red rays in the treatment of innumerable diseases. The subject has become so involved and highly technical and so much controversy exists over many of its important aspects that it seems futile to attempt to epitomize it in this limited presentation. The physiologic actions and indications for use of the visible and infra-red rays differ but little from those already discussed under the general and local application of heat. This is not true of ultraviolet radiation which, although it has been recommended for a large number of diseases in which it does no particular good, is nevertheless almost specific in rickets and tetany and of acknowledged merit in many cutaneous diseases and in calcium and phosphorus deficiency states. The empiricism that has been so conspicuous in light therapy must give place to more accurate scientific knowledge of the dosage of light radiation, the relative value of the innumerable types of therapeutic lamps and their proper application. It is gratifying to note that through its researches, the Council on Physical Therapy is doing outstanding work in the standardization of light therapy. The value of light radiation is undeniable, but it is not without its dangers, which should be more fully appreciated. Its indiscriminate use by those who know little of its physiologic effects should be controlled.

HYDROTHERAPY

Water in any of its forms is one of the most generally useful and easily available therapeutic agents. For centuries it has proved a valuable adjunct in the treatment of disease, yet among the medical profession hydrotherapy no longer enjoys the popularity it was once accorded.

It is a most flexible therapeutic agent which, as Krusen aptly puts it, "can be variously modified from the solid form (ice) to the liquid form, to the gaseous form (steam)." According to Baruch, who did so much to popularize this form of therapy in America, hydrotherapy in the broad sense includes the application of water in any and all of its various forms.

The stimulating, tonic and sedative effect of baths of varying temperatures and different mechanical forms is generally understood and needs no detailed discussion. There are, however, several aspects of hydrotherapy of particular interest to physicians.

The neuropsychiatrists have long appreciated the value of prolonged tepid or warm baths in the control of various maniacal states. A lesson could be learned from their experience, and hydrotherapy might be resorted to more often in the management of many forms of excitement and insomnia instead of overwhelming such patients with sedative drugs.

The chief physiologic effect of applying water to the body is to cause changes in temperature. This fact furnished a basis for the use of cold baths in the control of fever. The best example of this is the Brand bath or some of its modifications which did much to revolutionize the treatment of typhoid in the days when that infection was epidemic. The Brand bath is no more specific for typhoid than for any other infection characterized by long-continued fever and toxemia. Its effect is not primarily to reduce a rise in temperature so much as to improve the vasomotor tone, lessen the pulse rate, increase the blood pressure and control the nervous manifestations of the "typhoid state."

Medical baths have long enjoyed a curative reputation in many conditions. Whether the good results often recorded are due as much to the minerals in solution as to the effects of the water itself is a much debated subject. Among medicated baths the effervescing ones that contain nascent carbon dioxide, such as are found at Nauheim and elsewhere in Europe, are the best known and most useful. To obtain the benefits of such baths, it is no longer necessary to go to the spas where they occur in nature, since effective carbon dioxide baths can be readily prepared artificially. In certain types of cardiac disease, especially those in which there still remains a reasonable amount of cardiac reserve, the Nauheim bath if properly given and accompanied by suitable rest and exercise has proved of undoubted value. Here again is a form of hydrotherapy largely lost sight of which is capable of being of considerable clinical help to physicians.

It must be pointed out that the effectiveness of all forms of physical therapy may be greatly increased by the proper and intelligent combination of several procedures. Nowhere is this better exemplified than in the S. Weir Mitchell "rest treatment," in which the desired results were obtained by the combined use of rest, massage, exercise and hydrotherapy in conjunction with hypernutrition.

An essential and important adjunct to all forms of physical therapy is rest. The value of massage, exercise, heat and bathing is greatly enhanced when combined with adequate rest and relaxation and conversely is decidedly lessened when rest is neglected and states of fatigue are allowed to occur. This should not be lost sight of when physical therapeutic measures are employed. The physician should insist that they be carried out in a quiet, orderly fashion and that ample time be set aside for the rest by which they should be followed.

COMMENT

An effort has been made to stress certain methods of physical therapy that are based on sound physiologic principles, that are of acknowledged value and proved usefulness, that are readily available to all physicians and for the most part can be carried out with little difficulty even in the home. By so doing it is hoped that the interest of physicians in general, but those concerned in internal medicine in particular, may be revived in the far reaching possibilities of this broad therapeutic field. If physical therapy is to remain under the control of physicians and advance as it should along sound scientific lines, the indifference which the internists as a group have displayed in the past must give way to an active interest in developing a constructive, forward looking policy to improve the practice of and extend education in physical therapy.

2031 Locust Street.

ABSTRACT OF DISCUSSION

DR. JOHN S. COULTER, Chicago: It is gratifying to hear an internist comment favorably on the use of physical therapy. The Council on Physical Therapy of our association is trying to interest physicians to use simple physical agents in their practice. It is doing this by publishing articles in *THE JOURNAL* and through the *Handbook on Physical Therapy*, the fourth edition of which is now being prepared. This council is cooperating with the Council on Medical Education and Hospitals to increase the number of medical schools giving courses in physical therapy. One reason internists do not use physical agents in the treatment of patients as often as they should is that they feel sometimes that the expense is too great. In treating chronic diseases in which physical therapy is indicated, if physicians will arrange a home program of treatment the

patients will receive benefits from physical therapy that they would not otherwise. In the use of heat and massage to increase peripheral circulation or exercise to correct posture and increase muscle strength it is not enough to send a patient to a physical therapist once a day and expect to receive the maximum benefits. In treating such a disease as chronic arthritis with physical therapy it is advisable to instruct the patient or some member of the family to use physical therapy at home two or three times a day, in addition to the patient's visiting the physical therapy department. We recommend the use of simple agents, and the Council on Physical Therapy will be glad to send physicians designs for making many things, such as the home made electric lamp baker and exercise apparatus, so that physical therapy can be used without great expense and a home program of treatment established. I too want to emphasize that instructions for the use of physical agents must be carefully given. The instructions for home treatment should be as definite as for drug therapy. Mimeographed instruction sheets should be used for this purpose, and the Council will send, on request, samples of the instruction sheets that are used. In the present emergency the National Research Council has appointed a subcommittee on physical therapy to cooperate with and to advise the Surgeon Generals of the Army and the Navy, the Veterans Administration and the Public Health Service in the use of physical therapy in government hospitals. We hope there will be the same use of good physical therapy in this emergency as there was in the last.

DR. RALPH PEMBERTON, Philadelphia: I want to express satisfaction as an internist with this paper by Dr. Piersol, which seems to me to be timely. I have observed the physical therapeutic scene for many years, and from the standpoint of one interested in the influence of physical therapy on normal physiologic processes as well as on pathologic processes I have been amazed at the extraordinary neglect which we internists have accorded to this field. Dr. S. Weir Mitchell, who was fifty years ago one of the best clinicians and one of the best physiologists in the country, laid down principles in the use of physical therapy which have been followed to this day by the neurologists, by orthopedists and by others. But for some peculiar reason we internists have not taken cognizance of the effects which physical therapy will bring about, and by that I mean chiefly heat, massage, rest and exercise. It is also worthy of note that Jack Mitchell showed, forty years ago, that it is possible to increase the peripheral red cell count in some of the anemias by means of massage. Doubtless there are limitations to the extent to which anemia patients and perhaps cardiac patients should be subjected to such measures, but it is fair to say that there is enough of a nucleus of truth to justify the view that internists should utilize the influence of these factors more widely than they are now doing. Perhaps the most significant lesson to be deduced from Dr. Piersol's paper is the fact that he is speaking as vice dean for medicine of the Graduate School of the University of Pennsylvania, and I hope that his remarks will be regarded as a plea for more widespread instruction, undergraduate as well as graduate, in the principles of physical therapy.

DR. GEORGE MORRIS PIERSOL, Philadelphia: Dr. Pemberton has referred to the question of teaching physical therapy. Personal experience would indicate that the most difficult course to organize for graduate students in medicine is the one in physical therapy. You may comb a great metropolitan center and still find little available material to give students a constructive course along this line. The importance of the whole question of exercise and posture—Dr. Coulter has already stressed that—is evident to any one who has an opportunity to examine draftees for the Army. As a nation, faulty posture is one of our outstanding shortcomings. Among those nations in which mass exercise has been in vogue for many years the youth, instead of adopting the poor posture with which we are familiar, have acquired good posture and consequently are better prepared for military and similar services. Again it must be emphasized that all procedures in physical therapy, including those used in heart disease, must be looked on as adjuncts; not intended to replace well recognized forms of therapy, but as useful aids to them which, if employed more often, would tend to shorten convalescence and increase the well being of patients not only physically but also psychologically.

PNEUMONIA IN CHILDREN

A REVIEW OF SEVEN HUNDRED AND THIRTY-ONE CASES

CRAIG D. BUTLER, M.D.

NOEL G. SHAW, M.D.

SAMUEL J. HOFFMAN, M.D.

SOL DITKOWSKY, M.D.

EMERSON McVEY, M.D.

AND

MARY ZELDES, M.D.

CHICAGO

A review of pneumonia in 731 children entering Cook County Hospital from April 1939 through May 1940 has enabled us to collect valuable data and make numerous observations on a disease which has recently held the limelight because of new trends in therapy. In view of the type of patients who frequent such a hospital (all are indigent and many are malnourished children in the late stages of the disease) this has been a severe test for the efficacy of drug therapy.

The original plan of the pneumonia service¹ was to have a control series of patients receiving nonspecific therapy and a comparable group receiving specific serum or chemotherapy, but by the time sulfapyridine became available in sufficient quantities (April 1939) there had been satisfactory reports, experimental² and clinical,³ to warrant the use of the drug. It was deemed unwise to withhold specific therapy from acutely ill patients for the sake of statistics. The plan was therefore changed so that patients were treated according to the severity of the disease without any attempt to establish a control group. During the fourteen months of observation, 731 children from 1 to 13 years of age were studied and treated; only those with definite physical, laboratory and roentgen evidence of pneumonia were considered in this group.

PROCEDURE

Every child entering the Cook County Hospital for whom a diagnosis of pneumonia was made or suspected was referred to a special resident in charge of the pneumonia service. The resident confirmed the diagnosis and immediately (or, if the patient entered during the night, early the next morning) collected sputum for typing. Early in the series, sputum was collected by direct laryngoscopy; later satisfactory specimens were obtained from the lower part of the pharynx by gagging the patient with a tongue depressor. The mucopurulent material was collected on sterile swabs, placed in sterile test tubes and immediately taken to the nearby diagnostic laboratory of the Department of Health of the State of Illinois for typing and culture.⁴

From the pneumonia service of Dr. Butler and Dr. Hoffman from the Cook County Children's Hospital and the Departments of Pediatrics of Rush Medical College, the University of Illinois College of Medicine and the Cook County Graduate School of Medicine.

¹ Dr. Maurice L. Blatt, chief of staff, Cook County Children's Hospital, instituted a special pneumonia service to be supervised by Drs. Butler and Hoffman.

² Whitby, L. E. H. Chemotherapy of Pneumococcal and Other Infections with 2 (p-Aminobenzenesulfonamido) Pyridine, *Lancet* 1: 1210-1212 (May 28) 1938.

³ Evans, G. M., and Gaisford, W. F. Treatment of Pneumonia with 2 (p-Aminobenzenesulfonamido) Pyridine, *Lancet* 2: 1419 (July) 1938. Barnett, H. L., Hartmann, A. F., Perlev, Anne M., and Ruhoff, Mary B. Treatment of Pneumococcal Infections in Infants and Children with Sulfapyridine, *J. A. M. A.* 112: 518-527 (Feb. 11) 1939. MacColl, W. A. Clinical Experience with Sulfapyridine, *J. Pediatr.* 14: 277-289 (March) 1939.

⁴ Dr. H. S. Shaughnessy, chief of laboratories of the Department of Health of the State of Illinois, and his staff aided in the bacteriologic studies.

Blood cultures, complete blood counts, urinalyses and roentgenograms of the chest were ordered immediately.

For all severely ill children who were suspected of having or who definitely had pneumonia, treatment with sulfapyridine was instituted as soon as the clinical diagnosis was made, usually before the bacteriologic diagnosis was made. Those who later were shown not to have pneumonia were dropped from the series. Of the 731 children admitted with a diagnosis of pneumonia, 656 (87.1 per cent) received sulfapyridine, 19 (2.6 per cent) received serum in addition to the drug and 75 (10.2 per cent) received no specific medication because they were moribund or convalescent on admission.

The usual dose of sulfapyridine was 1½ grains (0.1 Gm.) per pound of body weight on the first day and

Unclassified	7	87.5	1	12.5
Not examined (2)

¾ to 1 grain (0.04 to 0.06 Gm.) per pound on subsequent days. Children over 6 years of age received somewhat smaller doses, but at least 1 grain (0.06 Gm.) per pound the first day and ½ grain (0.03 Gm.) per pound on subsequent days. The first two doses were larger (almost half of the calculated twenty-four hour requirement) than the following doses, in order rapidly to build up the concentration.

Fluids given parenterally, inhalations of oxygen and blood transfusions were administered freely when symptoms indicated their use. Specific antipneumococcus rabbit serum was given intravenously to patients not responding satisfactorily to chemotherapy after twenty-four to forty-eight hours of treatment.

ANALYSIS OF DATA

Of the 731 children studied, 54 per cent were boys and 46 per cent girls; 60 per cent were white and 40 per cent Negro. The racial incidence was in direct proportion to the total admissions to the hospital. It

Chart 1.—Monthly incidence of pneumonia, April 1939 to May 1940.

was of interest to note, however, that only 20 per cent of the deaths occurred in Negro children.

Diagnosis of lobar pneumonia and bronchopneumonia was made as accurately as possible by physical examination and roentgen studies. Forty-five per cent of the patients were classified as having bronchopneumonia and 55 per cent as having lobar pneumonia. Sex and race bore no relation to the incidence of the disease (table 1), but the expected variation with age occurred. In the group aged 1 to 2 years 68 per cent had bronchopneumonia, while in the group over 4 years of age 72 per cent had lobar pneumonia.

There was a pronounced variation by months in the number admitted to the hospital. The greatest number of patients with pneumonia were admitted in March and April 1940 and the fewest in the summer months of 1939 (chart 1). Studies on the mortality revealed that approximately 50 per cent of the deaths occurred from July to October 1939 (inclusive), when only 11 per cent of the patients were admitted.

In approximately 78 per cent of the cases there were pneumococci in the laryngeal swab. Other organisms,

TYPES	UNDER 4 YEARS OF AGE	OVER 4 YEARS OF AGE
TYPE I	25%	75%
TYPE II	67%	33%
TYPE III	15%	15%
TYPE XIV	75%	27%

Chart 2.—Age distribution of most prevalent types of pneumococcal pneumonia.

notably streptococci and staphylococci, were identified in 17 per cent, while in approximately 5 per cent no bacteriologic diagnosis was made (table 2).

An attempt was made to associate the bacteriologic with the pathologic types of pneumonia. In approxi-

mately 60 per cent of the cases of pneumococcal pneumonia the involvement was lobar, and in 40 per cent it was bronchial, while in 47 per cent of the cases of non-pneumococcal pneumonia the involvement was lobar and in 53 per cent it was bronchial (table 3).

As has been pointed out in other reports, the types of pneumococci most common in cases of pneumonia in children differ from those most frequently associated with pneumonia in adults. In our study, the four types of pneumococci most frequently recovered were types I, VI, XIV and XIX; together they accounted for 45 per cent of the cases of single strain pneumococcal pneumonia or for 28 per cent of the entire series. The incidence of the various types is shown in table 4.

Pneumococci of types I, II, III, VII and XIV were found most frequently in cases of lobar pneumonia, while types above XX predominated in cases of bronchopneumonia. Pneumococci of types VI and XIX were found with equal frequency in cases of lobar pneumonia and of bronchopneumonia. The percentages of the types of pneumococci are correlated with the existing pathologic process in table 5.

There was a distinct relationship between the strain, or type, of pneumococcus and the age group. Type I was found most frequently (chart 2) in the older age group (in which 75 per cent of the patients were over

4 years of age and approximately 80 per cent had lobar pneumonia). Type XIV was definitely associated with the younger age group (85 per cent of the patients were under 4 years of age); one would therefore expect bronchopneumonia to predominate in type XIV pneumococcic infections, whereas in 69 per cent of our cases

the involvement was classified as lobar. Approximately two-thirds of the patients with type VI and type XIX pneumonia were under 4 years of age and were equally divided among those with bronchopneumonia and those with lobar pneumonia.

Of the 731 cases under observation, cultures of blood obtained on admission were positive in only 32, or 4 per cent. Nine cultures revealed type I pneumococci, 7 staphylococci, 6 type XIV pneumococci, 3 streptococci, 2 type V, 2 type XXXIII, 1 type IV, and 1 type VII pneumococci, and 1 an unclassified pneumococcus. Many patients showed definite clinical evidence of sepsis, but 17 with positive blood cultures had no symptoms of bacteremia and were discharged from the hospital within eight days after admission.

The symptoms of onset and the course of the pneumonia prior to institution of therapy in no way differed in this series from the usual picture. One noteworthy feature was the individuality of type I pneumococcus pneumonia. The patients with this type were more toxic; vomiting, abdominal pain, delirium and meningismus occurred more frequently. Empyema occurred

eighteen times more often with this type than with all other forms of pneumonia. The mortality, however, was not greater than for the less severe forms.

Many patients were dehydrated and ketotic on admission. Approximately 60 per cent had acetone in the initial specimen of urine. Albuminuria occurred in 6 per cent and in 25 per cent of those with type I pneumonia. The majority of the patients had white blood cell counts above 10,000, but 26 per cent showed leukopenia. Twenty-one per cent had a level of hemoglobin below 60 per cent. The lowest hemoglobin readings were those for patients with non-pneumococcic pneumonia.

The most common complication encountered in the 731 cases of pneumonia was otitis media. This disease was considered a complication only when the drum was bulging and paracentesis yielded a purulent discharge. Catarrhal otitis media was not included among the complications. Suppurative otitis media occurred in 53 cases (7.4 per cent); the incidence was greatest in the younger age groups. Approximately 10 per cent of the children below 4 years, as compared with 3.5 per cent of those above 4 years, had this complication. Surgical intervention (other than paracentesis) was

TABLE 10.—Mortality of Pneumonia in Children

not required. The types of causal organisms are shown in table 6.

The second most frequent complication and the one of greatest severity was empyema. It occurred in 29 cases, or 4 per cent of all that were studied, and in 18 cases (62 per cent) of type I pneumococcus pneumonia. The types are shown in table 7. Bacteriologic examination of the empyema fluid offered an excellent opportunity for study of the accuracy of the typing from pharyngeal swabs. In 18 cases, the organism recovered from the empyema fluid corresponded to that previously recovered from the sputum. In 4 cases pneumococci (types III, V and IX and mixed types) had been reported in the specimen of sputum, but the pleural exudate in 2 contained streptococci and in 2 staphylococci. On the other hand, staphylococci were recovered from the throat in 1 and streptococci in 2 cases in which there later developed type I pneumococcus empyema. Pneumococci of types XIX and XXI, respectively, were found in the sputum in 2 cases of type I pneumococcus empyema, and pneumococci of type XIX were found in the sputum in 1 case of type V pneumococcus empyema. Using this small series as a test of the efficiency of sputum typing, in view of the fact that one third of the cases of pneumonia resulting in empyema were incorrectly diagnosed, one might conclude that sputum typing in our series was only 65 per cent accurate.

Among the 29 empyema patients 4 (14 per cent) died. One of these was a mongolian idiot whose blood culture showed pneumococci of type XIV. One had streptococcal sepsis secondary to mastoiditis, and another, with type V pneumococcus pneumonia, died on the day of admission. From the fourth child, a 2 year old infant with severe sepsis, a few cubic centimeters of pus was aspirated shortly before death; no bacteriologic report was received for this child. There seemed to be no benefit from chemotherapy after the empyema was established.

As has been previously stated, there was no attempt to alternate types of therapy in our series of cases. Sulfapyridine was used alone in 87 per cent and in conjunction with specific serum in 2.6 per cent; nonspecific therapy was used in 10.2 per cent. The average amount of sulfapyridine required to reduce the temperature to normal was 3.21 Gm. and the average total dose 6.17 Gm. The typical response, so well known now, was obtained in the majority of the cases. Of about 200 sulfapyridine-treated patients whose febrile response was analyzed, 34 per cent reached and maintained a normal temperature within twelve hours after the initiation of treatment, 66 per cent within twenty-four hours and 95 per cent within forty-eight hours (table 8).

The mild unfavorable reactions reported by other authors were encountered in our series. In 17 per cent of cases vomiting was of sufficient severity to be recorded on the nursing chart. It in no way interfered with the efficacy of the treatment, however, and was more annoying than it was serious. Hematuria due to irritation by acetylsulfapyridine crystals was recorded in 3.6 per cent of the cases. The urine cleared when the drug was discontinued. Acute cerebral manifestations were seen in approximately 2 per cent; these varied from coma to confusion and to delirium. In a few cases rash due to the drug was seen, and in 1 case hemolytic anemia occurred. No death could be attributed to the chemotherapy.

Twenty of the 731 children died, with a resulting mortality of 2.73 per cent. Nine died within the first twenty-four hours after admission. Two children were discharged from the hospital apparently well but returned a few weeks later; 1 died from multiple cerebral thromboses, and the other had a thrombosis of the inferior vena cava. The 9 children who died within the first twenty-four hours in most instances had terminal pneumonia on admission and died before any therapy could be instituted. The remaining 9 (1.33 per cent) died during treatment. All but 1 of the children who died were under 4 years of age; 12 were between 1 and 2, 5 were 3 and 1 was 5. Eight had lobar pneumonia and 10 bronchopneumonia, and 2 had a chronic interstitial type of pneumonia. The pathologic diagnosis was established by autopsy on 12. The types of organisms in the fatal cases are shown in table 9. Three of the deaths were of mentally defective children. It is interesting to note that only 1 death of a child with proved type I pneumococcus pneumonia occurred.

The 2.73 per cent mortality rate for the 731 cases presented was compared with statistics of previous years. In table 10 the mortality rates of a collected series cited by Abt in 1926 are compared with that for the Cook County Hospital in 1938 prior to specific therapy. In 1926, before the free use of fluids and blood transfusions, Abt showed that the mortality of children over 1 year of age for all types of pneumonia was 15 per cent and for lobar pneumonia 7 per cent. After

the advent of better general measures in the care of patients with pneumonia, in 1938, the mortality in the same age group was 6.6 per cent for all pneumonias and 3 per cent for lobar pneumonias.

SUMMARY

1. Of 731 cases of pneumonia in children aged 1 to 13 years, pneumococci were demonstrated in 78 per cent.
2. Pneumococci of types I, VI, XIV and XIX were the ones most frequently found.
3. Administration of sulfapyridine was the sole therapeutic measure in 87.1 per cent of the cases; serum and sulfapyridine were used in 2.6 per cent, and non-specific therapy was employed in 10.2 per cent.
4. Otitis media occurred in 7.4 per cent of the cases. It occurred most commonly in younger children and in association with type XIV pneumococcus infections.
5. Empyema occurred in 4 per cent of the cases. Type I pneumococci were recovered from the pleural exudate in 62 per cent.
6. The mortality rate was 2.73 per cent. When 2 children who died on readmission and 9 who died within the first twenty-four hours were excluded, the mortality rate was 1.33 per cent.
7. Type I infections presented the most severe symptoms and were most commonly complicated by empyema, but they had no higher a fatality rate than infections of other types.
8. Complications of treatment with sulfapyridine were encountered but were mild and did not interfere with the efficacy of the treatment.

TREATMENT OF THE MENOPAUSE

EVALUATION OF ESTROGEN IMPLANTATION

UDALL J. SALMON, M.D.

SAMUEL H. GEIST, M.D.

AND

ROBERT I. WALTER, M.D.

NEW YORK

During the past few years, the endocrine treatment of the menopause syndrome has become established on a firm, rational basis. This has been made possible by studies of numerous investigators clarifying the hormonal mechanism responsible for the menopausal symptoms and by the researches of the sterol chemists which made available highly potent preparations of ovarian hormones. The traditional concept of the menopause as an aberration of somatic function, predominantly psychogenic in origin and requiring only sedation and psychotherapy, has given way to the realization that the menopausal symptoms are primarily a manifestation of a hormone deficiency caused by a waning or cessation of ovarian activity and that rational therapy should consist of supplying the patient with the hormone she lacks. The therapeutic results obtained with estrogens in the menopause constitute one of the most gratifying and dramatic achievements of modern medicine. However, by virtue of the fact that administering estrogens is substitution therapy, the problem does not end with

Mr. A. Austin Salmon performed the gonadotropic hormone assays. From the Gynecological Service of Dr. S. H. Geist, Mount Sinai Hospital.

The materials used in this investigation were supplied by the Schering Corporation, Bloomfield, N. J., and Ciba Pharmaceutical Products, Summit, N. J.

Read before the Section on Pharmacology and Therapeutics at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

relief of the symptoms, since almost invariably discontinuation of the estrogens results in a recurrence of the symptoms. One must, therefore, make provision for adequate maintenance therapy if the patient is to be kept symptom free. The necessity for prolonged treatment focused attention on the problem of determining the most efficient method of administering estrogens.

There is considerable evidence which appears to indicate that the high dosage of estrogens required to relieve menopausal symptoms is, in great part, attributable to the rapid absorption and excretion of the hormone. To achieve a satisfactory therapeutic effect in a patient with an advanced degree of estrogen deficiency, it is necessary to administer injections of a solution of the hormone in oil, at frequent intervals, for periods of several weeks. Aside from the inconvenience caused the patient by the necessity for frequent injections, there is the additional factor of expense which places this form of therapy beyond the means of many patients. In the interests of economy and the patient's comfort, it would obviously be highly advantageous if one could administer the hormone in a form which would provide her, at a single administration, with a supply adequate for her needs for several months.

To this end we have been experimenting for five years with a variety of methods of administering estrogens. In 1938 we began a series of studies with the subcutaneous implantation of loose crystals of estradiol and obtained encouraging results.¹ Since then we have performed implantations in a total of 180 cases with either loose crystals or compressed pellets of various synthetic estrogens, androgens and combinations of the two. We present here the results of our experience with this method of estrogen administration.

LITERATURE

Deanesley and Parkes² in 1937 were the first to report the implantation method of administering sterol sex hormones in animals. In the following year, Bishop³ reported the implantation of a 14 mg. compressed pellet of theelin in a 20 year old surgical castrate and noted that the "hot flush frequency" curve began to descend in about one week and that, at the end of four weeks, the flushes began to increase again. Shortly thereafter, we¹ reported complete relief of menopausal symptoms, for as long as ninety-eight days, in a series of 10 cases in which implantations were made with loose crystals of α -estradiol. In subsequent reports, prolonged therapeutic effects following implantation with compressed pellets (46 cases), as well as loose crystals (55 cases), were described.⁴ It was also shown that "by means of the implantation of crystals of α -estradiol and α -estradiol benzoate, it is possible to achieve a strikingly more prolonged inhibition of the hypophysis in postmenopause and ovariectomized women than can be obtained by injection of comparable amounts of estrogenic compounds in solution in oil."⁵ At the Scientific Exhibit of the American Medical Association, held in New York in June 1940, our group presented the results of estrogen implantation in a series of 126 cases. At that time, good therapeutic effects were noted, in some cases for as long as twelve months. In the same year, Bennett, Biskind

and Mark⁶ reported a series of 21 cases in which multiple (3 to 10) pellets of estrone were implanted. Eighteen patients were relatively free of symptoms for periods of from two to fourteen weeks following a single implantation with from 3 to 10 pellets weighing 5 to 6 mg. each.

PROCEDURE

In order to appraise the therapeutic value of estrogen implantation accurately, we formulated a series of questions designed to cover the phases of the problem which are of clinical interest. These are:

1. Is implantation more efficient than other methods of estrogen administration?
2. What is the most effective estrogenic compound?
3. What is the most effective method of implantation (compressed pellets or loose crystals)?
4. What is the optimal dose?
5. Are there any undesirable clinical side effects?
6. What is the effect of prolonged estrogenic stimulation on (a) the genital tract, (b) the breasts and (c) the tissues in contact with the implanted hormone?

The following studies, designed to supply answers to these questions, were undertaken:

1. *Clinical Evaluation of Efficiency.*—The duration of symptomatic relief resulting from estrogen implantation was compared with the results of administration, to a control group, of similar amounts of estrogens of the same chemical constitution, in solution in oil.
2. *Objective Criteria of Efficiency.*—Because of the protean character of symptoms of the menopause and the individual variations in subjective evaluation of symptoms, we felt that, in addition to a clinical appraisal, it was imperative that some objective criteria of estrogen activity be used to estimate the efficiency of the estrogen implantation.
- The criteria employed were: (a) the duration of estrogenic effects on the endometrium and vaginal mucosa (as revealed by endometrial and vaginal biopsies and vaginal smears); (b) the duration of pituitary inhibition (as determined by excretion of the gonadotropic hormone).
3. With these criteria, the efficiency of α -estradiol, α -estradiol benzoate, α -estradiol dipropionate, and estrogens in oil were compared.
4. Employing the same standards, we conducted a comparative study of the merits of implanting the estrogens in the form of loose crystals and compressed pellets.
5. The rate of absorption of the hormone was determined by excision of the pellets at varying intervals after implantation.
6. Histologic (biopsy) studies of the endometrium and vaginal mucosa were performed and the tissues surrounding the implanted hormone were excised, at varying intervals after the implantation, to determine whether any abnormal proliferation had been induced.
7. The breasts were examined periodically for evidence of abnormal stimulation and neoplasms.

MATERIALS AND METHODS⁷

Our studies have been conducted on a series of 180 patients varying in age from 35 to 70 years, comprising instances of natural menopause and surgical and roentgen castration. The estrogens employed were α -estradiol, α -estradiol benzoate and α -estradiol dipropionate in the form of loose crystals and of compressed pellets.

Morphologic Studies.—Vaginal smears and biopsies were performed before implantation in every case; in cases of spontaneous and of roentgen menopause, preliminary endometrial biopsies were also taken. The vaginal smears were prepared by the aqueous fuchsin

method.⁸ Vaginal biopsies were taken from the lateral wall of the upper two thirds of the vagina; endometrial specimens were obtained with the suction curet and stained with hematoxylin and eosin.

Vaginal smears were taken two or three times a week during the first two weeks after implantation; thereafter at intervals of one to two weeks. Vaginal biopsies, in the majority, were taken at intervals of two to eight weeks; material for endometrial biopsies were not taken uniformly from all patients. In a few selected cooperative patients suction curettages were performed at two week intervals; in others, at four to eight week intervals. One patient had a series of twelve biopsies taken during a period of seven months.

Gonadotropic Hormone Studies.—Urinary gonadotropic hormone extracts were prepared by a modification of the acetone precipitation method.⁹ In 37 cases, assays were performed on twenty-four and forty-eight hour specimens for from six to nine consecutive days preceding the implantation; after the implantation, in 25 cases, gonadotropic assays were done at intervals of from seven to fourteen days; in 12 of the 37 cases, assays were performed continuously on

* The percentage figures beyond four months were calculated on the basis of the number of patients observed for the specified length of time.

forty-eight hour urine specimens for periods varying from thirty to two hundred and seven days after the implantation.

CLINICAL RESULTS

In table 1 are shown the clinical results observed in 126 patients following various types of estrogen implantation. It will be noted that 5.5 per cent of the patients were given no relief by the implantation; that 94.5 per cent were symptom free two months after the implantation, that at the end of four months 82 per cent, at the end of six months 63 per cent, and at the end of twelve months 33 per cent were still symptom free. The patients in the latter group are still being observed; some are still symptom free at the end of two years.

In table 2, the clinical results obtained with three chemically different estrogens, administered in the form of implants of crystals, pellets and injections of estrogens in oil, are shown.

Estradiol Crystals.—The total number of patients implanted with estradiol crystals was 42. These included 19 in natural menopause, 5 roentgen castrates and 18 surgical castrates. The dosage was varied from 5 to 50.6 mg.

Seventeen patients were implanted with doses varying from 5 to 10 mg. The duration of symptomatic relief varied from two to upward of twenty-four months. All the patients in this group were symptom free for a minimum of two months. At the end of twelve months, 40 per cent were still symptom free.

Twenty-three patients were implanted with doses varying from 20 to 30 mg. The duration of symptomatic relief varied from a minimum of five months to upward of twenty-four months. At the end of nine months, 44 per cent and, at the end of twelve months, 33.3 per cent of the patients were still symptom free. Two patients (not included in the table) who were implanted with 50 and 50.6 mg. of α -estradiol, respectively, were free of symptoms at the end of six and a half and seven months.

Estradiol Pellets.—In this group, 27 patients (17 in natural menopause, 4 roentgen castrates and 6 surgical castrates) were implanted with pellets varying in weight from 15 to 30 mg. Three patients experienced no relief. In the remaining 24, duration of relief varied from two to upward of twenty months. At the end of three months 85 per cent, at the end of six months 46 per cent and at the end of twelve months 25 per cent were still symptom free.

Estradiol Benzoate Crystals.—Nineteen patients (10 in natural menopause and 9 surgical castrates) were implanted with estradiol benzoate crystals in doses varying from 18 to 36.6 mg. One patient was not relieved. Of the remaining 18, the duration of relief varied from three to twelve months. All 18 patients were symptom free at the end of three months. At the end of six months 37 per cent and at the end of twelve months 7 per cent were still symptom free.

Estradiol Benzoate Pellets.—Twenty-two patients (9 in natural menopause, 4 roentgen castrates and 9 surgical castrates) were implanted with pellets of estradiol benzoate, varying in weight from 25 to 50 mg. Three patients experienced no relief. The duration of relief reported by the remaining 19 patients varied from two to seventeen months. At the end of three months 64 per cent, at the end of six months 50 per cent and at the end of twelve months 24 per cent were still symptom free.

Estradiol Dipropionate Crystals.—Twelve patients (5 in natural menopause, 3 roentgen castrates and 4 surgical castrates) were implanted with estradiol dipropionate crystals in doses varying from 18 to 25 mg. The duration of relief of symptoms varied from two to thirteen months. At the end of three months 75 per cent, at the end of six months 33 per cent and at the end of twelve months 17 per cent were still symptom free.

Estradiol Dipropionate Pellets.—Four patients were implanted with estradiol dipropionate pellets varying in weight from 24 to 31 mg. This group has been followed for only three months. All have remained symptom free during this period of observation.

INCIDENCE OF UTERINE BLEEDING

Estradiol Crystals.—No bleeding occurred in the patients implanted with the small doses of 5 to 10 mg. of estradiol crystals. Of the 23 patients in this series, 11 had had hysterectomies. Of the remaining 12 patients, 7 had one to five episodes of uterine bleeding. Bleeding occurred from one to five months after the implantation and varied from a moderate flow, lasting several days, to several weeks.

Estradiol Pellets.—Bleeding occurred in only 3 of the 21 patients with uteri in this group. The amount and duration of the bleeding was much less than in the group implanted with estradiol and estradiol benzoate crystals.

8. Salmon, U. J., and Frank, R. T.: Proc. Soc. Exper. Biol. & Med. 33: 612, 1936. Geist, S. H., and Salmon, U. J.: Am. J. Obst. & Gynec. 35: 392, 1939.

9. Modification of the Acetone Precipitation Method, to be published. Walter, Geist and Salmon."

Estradiol Benzoate Crystals.—Bleeding occurred in 7 out of 10 patients. In this group the bleeding was comparable in amount and duration to the bleeding in the estradiol crystal group.

Estradiol Benzoate Pellets.—No bleeding occurred in this group.

Estradiol Dipropionate Crystals.—Four of the 8 patients in this group, with uteri, had bleeding episodes which were comparable in amount and duration with the estradiol crystal (20 to 30 mg.) group.

Estradiol Dipropionate Pellets.—One out of the 4 patients in this group had a moderate amount of uterine bleeding six weeks after the implantation.

EFFECT OF ESTROGEN IMPLANTATION ON
THE ENDOMETRIUM

Pretreatment biopsies in all instances revealed various degrees of hypoplasia or atrophy. Postimplantation biopsies in the group implanted with crystals of estradiol or estradiol benzoate manifested proliferative changes within one week after implantation, and the endometrium progressed to a state of hyperplasia at the end of one month which persisted for approximately three and one-half months; moderate proliferation per-

months, the vaginal mucosa began to show regressive changes. Although the tempo of this retrograde process varied, in the majority the vaginal mucosa returned to the preimplantation state at approximately six to seven months after the implantation.

In the majority of the pellet group, the high level of full estrogenic stimulation was maintained for a shorter period, some patients showing complete regression at the end of three months. It is worthy of note that in a number of this group pellets weighing as much as 48 mg. were found encapsulated in the subcutaneous tissue at the time the vaginal mucosa revealed evidence of severe estrogen deficiency.¹⁰

GONADOTROPIC HORMONE EXCRETION STUDIES

A property of estrogens which lends itself to objective evaluation is the capacity of the hormone to inhibit the hyperactive hypophysis in estrogen-deficient women. Using the duration of hypophysial inhibition as a measure of estrogen activity, we have attempted to compare the relative effectiveness of the various implanted estrogens. In previous communications we¹¹ have reported that by means of the implantation of crystals of α -estradiol and α -estradiol benzoate it is possible to achieve

TABLE 2.—Duration of Symptomatic Relief After Various Types of Estrogen Implantation and Intramuscular Administration of Estrogens in Oil

sisted for several months. In the majority of instances, the endometrium revealed regression to the preimplantation status at the end of approximately seven months.

In the group implanted with α -estradiol and α -estradiol benzoate pellets, the proliferative response in the endometrium was slower in development and less intense, hyperplasia being found in only 1 instance. Evidence of estrogenic stimulation in the form of moderate endometrial proliferation persisted for from four to six weeks, after which regressive changes were noted. The tempo of regression varied, the endometrium returning to the preimplantation status within from three to six months after the implantation.

EFFECT OF ESTROGEN IMPLANTATION ON
VAGINAL MUCOSA

Pretreatment vaginal biopsies and smears revealed, in all instances, various degrees of estrogen deficiency. Estrogenic effects were noted within four days after all types of implantations. The vaginal mucosa of those implanted with α -estradiol and α -estradiol benzoate crystals, however, revealed estrogenic effects somewhat earlier and of more intense degree than the group implanted with pellets of comparable weight and similar chemical constitution.

The high level of full estrogenic stimulation, as indicated by proliferative changes in the mucosa, was maintained, in the group implanted with crystals, for periods varying from three to four months. After four

a prolonged inhibition of the hypophysis of postmenopausal and castrated women. Further studies have shown that implanted crystals are strikingly more effective than pellets (of the same weight and chemical constitution) in inhibiting the hypophysis. Neither α -estradiol nor α -estradiol benzoate pellets were able continuously to inhibit the excessive excretion of gonadotropic hormone for longer than eight days. In contrast to this, patients who had been implanted with estradiol or estradiol benzoate crystals showed continuous inhibition for periods varying from fifty-seven to two hundred and eleven days.

EFFECT OF ESTROGEN IMPLANTATION ON
THE BREASTS

The majority of patients implanted with crystals noted a sensation of fullness of the breasts associated with swelling and tenderness of the nipples. Usually, this occurred at the end of the second or third week after the implantation. Examination of the breasts of all patients revealed a diffuse engorgement, as well as erection and redness of the nipples and areolas. The majority of the patients were of the opinion that the engorgement was similar, but rather more intense, than that which they had experienced preceding a menstruation period. These symptoms usually lasted for periods varying from two to four weeks. Breast engorgement occurred in relatively few of the patients

10. Geist, Walter and Salmon.¹² Walter, Geist and Salmon.¹³
11. Salmon, Geist and Walter.³ Geist, Walter and Salmon.¹²

implanted with pellets, and in these the symptoms were much less severe and of shorter duration. To date, in none of the implanted patients has there been any palpable evidence of neoplastic changes in the breasts.

LOCAL TISSUE REACTION TO ESTROGEN IMPLANTATION

The implantation sites of 38 patients were excised at periods varying from five days to fourteen months after implantation.

Capsule Formation About Implanted Pellets.—Pellets excised two months or longer after the implantation were found to be enveloped by a thick, avascular, fibrous capsule. The connective tissue adjacent to the implanted substance revealed a typical foreign body reaction.¹²

It is highly significant that in a number of instances, in spite of the presence of pellets varying in weight from 10 to 48 mg., in the subcutaneous tissue at the time of excision, endometrial and vaginal biopsies revealed histologic evidence of estrogen deficiency. Apparently, the fibrous capsules prevented absorption of the hormone in effective amounts.¹³

Tissue Reaction to Implantation of Crystals.—In contrast to the tissue reaction about the pellets described, no capsule was found at the site of implantation of the loose crystals. Microscopic examination revealed numerous tiny nodules, consisting of small central clear spaces divided by a fine connective tissue lattice-work surrounded by a zone of leukocytes, lymphocytes and foreign body giant cells.

RATE OF ABSORPTION OF ESTROGEN FROM IMPLANTED PELLETS

Nineteen patients (10 implanted with α -estradiol and 9 with α -estradiol benzoate) had the pellets excised at periods of time varying from five to two hundred and forty-five days after the implantation. In the α -estradiol group, the average absorption per day was 0.038 mg.; in the α -estradiol benzoate series, 0.027 mg. A slow rate of absorption is a desirable property, but it ceases to be an advantage if the rate of absorption becomes so slow that the physiologic requirements of the body are not met. This happens with both α -estradiol and α -estradiol benzoate pellets as a result of the formation of the fibrous capsule. The role of the capsule in retarding and finally preventing absorption of the hormone in effective amounts is stressed, since pellet implantation has been advocated in the treatment of the menopause.⁶ Although, as shown by these and other studies, the initial therapeutic results obtained with pellets are satisfactory, it should be borne in mind that absorption of the hormone in effective amounts ceases when only a small fraction of the pellet has been absorbed, so that, after several months, the patient retains an encapsulated pellet without deriving any therapeutic benefit from it.

EVALUATION OF INJECTIONS OF ESTROGEN IN OIL

A control series of 10 patients was given a single injection of 25 mg. each of α -estradiol benzoate and 8, 25 mg. of estradiol dipropionate, in solution in sesame oil. The effectiveness was measured by duration of symptomatic relief, as well as by the period of estrogenic effects on the endometrium and vaginal mucosa, and by suppression of gonadotropic excretion.

Two patients were only slightly relieved of their symptoms; the remaining 16 had symptomatic relief for periods varying from three to eight weeks. Estrogenic stimulation of the vaginal mucosa and endometrium varied from three to four weeks. Excretion of gonadotropic hormone was suppressed for periods varying from nine to eleven days. The brief duration of these estrogenic effects (both clinical and morphologic) stand in sharp contrast to the prolonged effects resulting from estrogen implantation.

PROPHYLACTIC IMPLANTATION OF ESTROGENS

Following the demonstration of the prolonged therapeutic effects of estrogen implantation, it seemed logical to use estrogen implantations prophylactically in women who were subjected to bilateral oophorectomy. During the course of a study of the psychic and somatic effects of ovariectomy, we found that not infrequently women have menopausal symptoms during the first postoperative week. That these symptoms are not psychogenic and actually constitute a somatic reaction to deprivation of estrogenic hormone is indicated by the fact that excessive excretion of gonadotropin (expressive of hyperactivity of the hypophysis) was found as early as three days after bilateral ovariectomy.¹⁴

A series of 36 patients was implanted with pellets and crystals of estradiol, estradiol benzoate and estradiol dipropionate, either at the time of oophorectomy or within a few days thereafter. The postimplantation period of observation in this series varied from three to twenty-four months. During the first three months after implantation in only 1¹⁵ of the thirty-six patients did symptoms develop. During the following nine months, 20 patients had very mild flushes. Only 6 of the 20 patients had symptoms that became severe enough to require additional estrogen therapy. Sixteen patients have continued to remain free of symptoms during the entire period of observation, which extended to twenty-four months.

Appraisal of the prophylactic value of implantation in these patients is made difficult by the fact that it is impossible to know in how many of these patients symptoms would have developed without estrogen therapy. However, it is significant that in a control series of 88 untreated patients, 26 per cent had symptoms at the end of the first postoperative week, the incidence mounting rapidly during the following six weeks, at which time 81 per cent had symptoms; at the end of sixteen weeks, 92 per cent had typical symptoms.

The convalescence of the implanted patients appeared to be smoother, the usual postoperative asthenia and depression being distinctly less in evidence.

EFFECT OF ESTROGEN IMPLANTATION ON DIABETES IN MENOPAUSAL WOMEN¹⁶

It has recently been reported that administration of estrogen improves the carbohydrate tolerance and decreases the insulin requirement of menopausal diabetic women.¹⁷ In a series of 18 menopausal diabetic

women whom we implanted with estrogens, only 1 showed any improvement in the carbohydrate tolerance and insulin requirement. The results of this study are being reported elsewhere in detail.

COMMENT

Clinical Evaluation of Effectiveness of Estrogen Implantation.—Before implantation, all the patients in the series had complained of the usual menopausal symptoms, the most prominent and constant of which were flushes. Other symptoms, such as vertigo, weakness, headaches, palpitation, nervousness, insomnia, pruritus vulvae, arthralgias and arthritis, were present in various combinations in different patients. Because of variations in the incidence and intensity of these symptoms and their variable response to therapy, it was found impossible to compare the therapeutic effectiveness of the administered estrogens with regard to amelioration of these symptoms. Therefore, because of the occurrence of flushes in all the patients and the ability of patients to keep an account of their frequency, the amelioration of this symptom was selected as an index of therapeutic effectiveness.

In many instances, relief of flushes occurred as early as twenty-four hours after the implantation. With the few exceptions who were not relieved at all, the majority were almost completely relieved of flushes at the end of one week. Many of the associated menopausal symptoms, namely headaches, dizziness and weakness, were relieved at the same time as the flushes. The symptoms most resistant to treatment were the arthralgias. In only a relatively small number of cases were these relieved. The most rapid therapeutic effects were noted in patients implanted with crystals.

It is interesting to note that the 7 patients who experienced no relief of symptoms after implantation all showed morphologic evidence of estrogenic stimulation. The therapeutic failure of the implantation in these cases draws attention to two important aspects of menopause therapy: first, that estrogens alone are, in some patients, therapeutically ineffective and that such patients frequently respond to androgens;¹⁸ second, that in a number of patients the persistence of symptoms can be traced to psychogenic factors. The incidence of initial failures encountered with the various types of implantations should not, therefore, be construed as a gage of their relative therapeutic merits, since the role played by psychogenic factors was not evaluated in these patients before the implantation.

A number of these refractory cases were subsequently investigated and found to present neuropsychiatric disorders which, in the opinion of the psychiatrists, may account for persistence of symptoms. Realizing the importance of evaluating the degree to which collateral psychosomatic phenomena may color the symptomatology before and after treatment, we have undertaken a series of psychiatric studies of this aspect of the menopause problem.¹⁹ The results of this investigation are to be reported in the near future.

At the beginning of this study, a number of questions were formulated which were designed to determine the practical value of estrogen implantation as a therapeutic measure. The results of these studies supply the answers to these questions.

1. *Is the implantation method more efficient than other methods of estrogen administration?* A survey of the therapeutic results two months after implantation reveals that all forms of estrogen implantation are indisputably superior to the intramuscular injection of comparable amounts of the hormone in oil. Thus, only 1 of the 18 patients treated with estrogens in oil was symptom free at the end of two months, whereas the percentage of symptom free patients in the implanted series at the end of two months varied from 100 (estradiol crystals) to 73 (estradiol benzoate pellets).

2. *What is the most effective estrogenic compound?* Inventory of the therapeutic results at the end of five months reveals that the α -estradiol crystals were the most effective of the three estrogenic substances employed. All the patients in this group were symptom free for five months, whereas in the others the percentage of symptom free patients at the end of five months varied from 50 to 56.

3. *What is the most effective method of implantation (crystals or pellets)?* Judged by (a) the degree and intensity of symptomatic relief, (b) the intensity and duration of estrogenic activity (as indicated by proliferative changes in the endometrium and vaginal mucosa) and (c) the duration of hypophyseal inhibition, estrogens in the form of loose crystals are more efficient than compressed pellets of the same chemical constitution and comparable weight.

4. *Are there any undesirable clinical side effects?* Effect on Breasts: Tenderness and pain in the breast and uterine bleeding were the only undesirable clinical effects noted. Both of these phenomena also occur, not infrequently, following other methods of estrogen administration. Furthermore, the breast reactions in the implanted patients were of short duration (approximately two to six weeks) and caused only mild discomfort.

Uterine Bleeding: The uterine bleeding, however, is a collateral effect which may be annoying to both the patient and the physician. In older women it may arouse fears of a uterine malignant growth. Furthermore, the possibility of a uterine malignant growth occurring coincidentally must be considered and excluded in each instance by thorough curettage. It is worthy of note that the highest incidence of bleeding (approximately 65 per cent) occurred in the patients implanted with the larger doses of estrogen crystals (25 to 30 mg.), whereas no bleeding occurred in the group of patients implanted with small doses of estrogen crystals (5 to 10 mg.). Apparently the incidence of bleeding mounts with an increase in the amount of hormone implanted and is evidently a function of the degree of estrogenic stimulation of the endometrium. The optimal dose obviously would be an amount which would give a maximal therapeutic effect with a minimal incidence of uterine bleeding.

5. *What is the optimal dose?* The results of these studies indicate that the optimal dosage lies between 10 and 25 mg. of α -estradiol crystals. Further studies are being conducted to define this dosage more accurately.

6. *What is the effect of prolonged estrogenic stimulation on (a) the genital tract, (b) the breasts and (c) the tissues in contact with the implanted hormone?* As indicated by the endometrial and vaginal biopsy studies, the implanted estrogens produce a prolonged and intense proliferative reaction in these tissues. It

18. Salmon, U. J.: J. Clin. Endocrinol. 1:162, 1941. Geist, S. H., and Salmon, U. J.: New York State J. Med., to be published.
19. This study is being conducted in collaboration with Drs. Lawrence Kubie, Samuel Atkin and Isidore Silbermann.

should be borne in mind that these proliferative effects were limited in duration and that the endometrium and vaginal mucosa spontaneously regressed in all cases to the preimplantation state of quiescence within six to seven months.

The question naturally arises as to whether the intense estrogenic stimulation may not possibly have a carcinogenic effect on the genital tract and breasts. For obvious reasons this question cannot, at this time, be answered categorically. If a neoplastic type of proliferation were induced as a result of the estrogen implantation, it is logical to expect that abnormal changes would occur during the period of maximal or, at any rate, active estrogenic stimulation. It is worthy of note, therefore, that during the course of this study, which covers a period of more than two years and which exceeds the period of active estrogenic stimulation by many months, evidence of neoplasia was not found either in the vaginal mucosa or in the endometrium.²⁰ Furthermore, no evidence of neoplastic proliferation was found in the tissue contiguous with or adjacent to the implanted estrogens, and in no instance was there any clinical evidence of neoplastic changes in the breasts.

On the basis of the results of this study, it would appear that implantation is a practical, efficient and safe method of administering estrogens and that the implantation of estrogens, at the time of bilateral oophorectomy, is a prophylactic measure of great value because of its somatic as well as its psychotherapeutic effects.

SUMMARY AND CONCLUSIONS

1. Implantation with loose crystals and compressed pellets of α -estradiol, α -estradiol benzoate and α -estradiol dipropionate was carried out on a series of 180 patients.

2. A control series of 18 menopausal patients was given a single injection of comparable amounts of estrogen in solution in oil.

3. The efficiency of the implantation was evaluated on the basis of (a) degree and duration of symptomatic relief; (b) intensity and duration of estrogenic activity, as indicated by proliferative changes in the endometrium and vaginal mucosa, and (c) duration of hypophyseal inhibition, as indicated by suppression of gonadotropic hormone excretion.

4. Judged by the foregoing criteria, the implantation of estrogens in the form of loose crystals or compressed pellets is more efficient than the injection of comparable amounts of hormone in oil.

5. Loose crystals of α -estradiol and α -estradiol benzoate are more effective than the compressed pellets of the same chemical constitution. The longest period of symptomatic relief was obtained by the implantation of α -estradiol crystals.

6. Subcutaneous implantation of estrogens in the form of loose crystals of α -estradiol, in amounts varying from 10 to 25 mg., is a simple, safe and efficient method of administering estrogens in the treatment of symptoms attributable to estrogen deficiency resulting from surgical or roentgen castration or the natural menopause. It is also recommended as a prophylactic procedure at the time of bilateral ovariectomy because of its beneficial somatic and psychotherapeutic effects.

BENIGN AND MALIGNANT GIANT-CELL TUMORS OF BONE

DIAGNOSIS AND RESULT OF TREATMENT

HENRY W. MEYERDING, M.D.

ROCHESTER, MINN.

All giant-cell tumors were considered at one time to be malignant lesions and were classified by the term "giant-cell sarcoma." As knowledge concerning their true nature increased, it became evident that some of them were benign lesions and curable by means of surgical removal. I believe that the term "giant-cell sarcoma," when used in reference to benign giant-cell tumor, has been partly responsible for the confusion that has existed in the classification and study of this particular group of bone lesions. In a previous publication I¹ suggested the use of the terms "benign giant-cell tumor" and "malignant giant-cell sarcoma" in an attempt to clarify the differentiation.

Although surgical treatment resulted in many cures of patients who had these tumors, I became wary in my prognosis for I found that occasionally there was recurrence of the lesion, and in some instances metastasis occurred. Some physicians concluded that meddlesome surgical intervention and irradiation were responsible for the transition of the benign group into the malignant group, whereas others believed that the malignant condition was present in the beginning but had not been recognized. In some cases in which the lesion has been long standing, a malignant change may occur and regions of typical benign giant cells, composing most of the tumor, may show smaller foci of malignant cells. The degree of malignancy in such instances apparently is of low grade and the prognosis correspondingly better than in such bone lesions as osteogenic sarcoma. The radiologists have discovered this type of tumor to be radiosensitive and have reported cures after irradiation. Pathologists have found similar microscopic tissue present in cases of osteitis fibrosa cystica, of giant-cell tumor and in the generalized skeletal disease found in hyperparathyroidism.

The physician in charge of the patient on whom a diagnosis of tumor of the giant-cell type has been made therefore must take into consideration several factors in differentiating the true nature of the lesion. Invariably the roentgenograms give him the greatest aid by demonstrating the size, rapidity of growth, location, osteoclastic character, penetration or invasion of soft tissue and the earliest evidence of pulmonary metastasis. Roentgenographic examination of the thorax to exclude possible pulmonary metastasis is our routine procedure. The chemist further assists him in determining the concentration of calcium in the serum when greater than 9 to 11 mg., of phosphorus when less than 3 mg., and of phosphatase when greater than 5 units per hundred cubic centimeters and presence of excessive calcium in the urine by the Sulkowitch test, the type of lesion found in hyper-tumor of the parathyroid may be discovered on palpation or when an exploratory operation is performed on the parathyroid glands. In the work at the Mayo Clinic it has been our habit to

cooperate closely with the roentgenologist, the pathologist, the chemist and the endocrinologist so that we may give our patient an accurate diagnosis, which is essential to the institution of the proper method of treatment and which offers him the best prognosis in this particular lesion.

In large medical centers the study and analysis of the accumulated material permit the publication of much useful information concerning the diagnosis, treatment and prognosis, thus making it available to the general practitioner and surgeon. No one physician in private practice could expect to see, during a natural span of life, a sufficient number of patients who have rare bone lesions to permit him to obtain enough material on which to base conclusions. The generalized bone lesions of hyperparathyroidism, epulis of the jaw and osteitis fibrosa cystica, although all doubtless are allied closely to this lesion, are not included here as typical giant-cell tumors of benign or malignant nature, which are commonly located in the region of the epiphysis. The Bone Sarcoma Registry recognizes, in the recent classification, a malignant group and a benign epiphyseal giant-cell tumor group.

Of the 124 patients with giant-cell tumor seen at the Mayo Clinic during the quarter of a century from

1916 to 1940 inclusive, in 101 the lesions were benign and in 23, or 19 per cent, they were malignant. Simmons² in his study found that, in 8 per cent of the cases of giant-cell tumor, in which the treatment was conservative, metastasis subsequently developed. Coley³ reported a series of 50 cases in which the diagnosis

was benign giant-cell tumor and subsequently 10 patients, or 20 per cent, died of metastasis. The importance of a thorough and expert pathologic examination is therefore obvious, and it has been our practice to have these tumors examined by means of frozen section technic at the time of operation and rechecked in permanent sections later. By this means we have been able to differentiate the benign from the malignant lesion and thus govern the choice of treatment to be employed. It must be remembered that not all giant-cell tumors are suitable for surgical treatment and that in certain instances irradiation is the method of choice. I am convinced that the clinical diagnosis and roentgenologic diagnosis may not always be correct and that, although a high percentage may be correct when made by the expert, it is far better to have the corroboration of the pathologist's diagnosis.

BIOPSY

I further believe that the added advantage of a microscopic diagnosis far offsets any danger which may be ascribed to biopsy. In 4, or 3 per cent, of our cases

herein reported, biopsy alone was done and the patient returned home to carry out treatment there. Three lesions were benign and one was malignant. All patients in this group were living five or more years after biopsy.

Table 1 shows the distribution of patients by age and sex, table 2 the location of the tumor, table 3 the duration of symptoms and table 4 the previous treatment of the patients.

IRRADIATION

We do not practice the routine preoperative irradiation of all patients who have tumor of bone nor do we practice a period of watchful waiting, as during such time metastasis may occur and thus the opportunity of a cure may be lost. Rather it is our aim to establish a diagnosis, to determine the benignancy or malignancy of the tumor and to adopt the method of treatment which in our experience has proved most satisfactory. Therefore a detailed history and careful laboratory and roentgenologic studies permit a preliminary diagnosis, after which the patient is informed of our desire to verify our opinion by examining a section of tissue microscopically and consent is obtained to proceed with treatment that may be indicated. In those cases in which the lesion is inoperable, irradiation is carried out.

In our practice it is evident that irradiation has won a distinct place in the treatment of patients who have these tumors, since 23, or 19 per cent, of our series, were so treated, and it is gratifying indeed to see some of the excellent results that have occurred in appar-

² Simmons, C. C. Primary Malignant Bone Tumors. Differential Diagnosis—Its Importance in the Selection of Treatment. *Am. J. Surg.* 27: 19-25 (Jan.) 1935.
³ Coley, W. B. Prognosis and Treatment of Giant Cell Sarcoma. Based on a Further Study of End Results in Sixty Nine Cases. *Ann. Surg.* 56: 641-665 (Nov.) 1927.

ently rather hopeless cases. We have kept an open mind regarding the relative value of various methods of treatment. We believe that in the majority of instances surgical treatment offers by far the most rapid and certain cure. Occasionally soft and osseous tissues have been damaged by preliminary irradiation with resultant actinodermatitis and ulceration, which make surgical treatment difficult or inadvisable. Certainly irradiation of patients who have tumor of bone should be supervised by experts in roentgen therapy. I believe that irradiation used alone or in combination with surgical treatment will prove of increasing value in selected cases of benign giant-cell tumor and of malignant giant-cell sarcoma.

EXCISION BY CURETTAGE

Curettage of a giant-cell tumor should consist of complete excision, and in order to accomplish this it is necessary to have a dry field in which to work and a large enough opening so that the magnitude of the lesion may be determined and every particle of tumor tissue removed. After excision by curet, the wound

should be wiped dry and washed thoroughly with physiologic solution of sodium chloride or mild antiseptic solution; the surgeon should bear in mind that the mechanical action of the fluid will wash out invisible particles. Phenol then is swabbed over the dry surface and followed by the use of sponges dampened with alcohol, which should aid in eliminating the danger of remaining tumor tissue. The tissues then are closed snugly layer by layer and pads and compression bandage applied. Ordinarily there will be little bleeding. The use of drains may lead to infection and a prolonged convalescence. Amputation has been found necessary in those cases in which the tumor was large with ulcerating dermatitis or in which infection had occurred. I have used packs in the cavity after removal of the large tumor, sutured the wound snugly and then removed the packs in a second operation, after which homogenous bone was inserted. A large cavity is never drained after excision. This method of excision alone has been used with 100 per cent good results; in 7 cases, in all of which the lesion was benign and in which the patient was traced five or more years, he had lived five or more years. This method is more obviously adapted to the smaller tumors in the benign group.

EXCISION AND IRRADIATION

Excision followed by irradiation has gained in popularity, and in our series it was employed in 23, or 19 per cent, of the cases of the entire group (table 5). Certainly the surgeon who has done his utmost in removing the tumor but is in doubt about the com-

pleteness of the excision is justified in employing post-operative irradiation that may insure a good result. This method, when used in cases in which there is a low degree of malignancy, should show improved prognoses. In the group in which the lesion was benign, 16 patients were operated on five years or more before

this study was made, all of whom were traced and were living when the study was made, thus giving a five year survival rate of 100 per cent. In the group in which the lesion was malignant, there were 5 patients on whom this procedure was performed five years or more before the study was made. All of them were traced and 3, or 60 per cent, had lived five years or more.

EXCISION AND BONE GRAFTING

An increasingly valuable method of treatment and one that requires especial technical knowledge is the complete excision of the tumor followed by immediate filling of the defect with bone grafts. This method assures more accurate diagnosis, since it permits microscopic diagnosis from frozen tissue. The tumor is removed entirely and the cavity filled with autogenous bone grafts, thus assuring the most rapid and accurate filling of the defect. Indeed the patient has a minimal loss of time and in most instances is assured an excellent functional result. During recent years excision with bone grafting has been my favorite method of treatment of patients who had giant-cell tumor of

* Inquiry as of 1941. The five year group comprises the patients whose diagnoses were made five years or more prior to the time of inquiry; that is, 1935 or earlier.

bone, and needless to say it has given the most gratifying results. The larger tumors, which have challenged the surgeon in the past, are now approached with greater confidence as he knows he will often save the limb and the patient will obtain a good result, which was not possible prior to insertion of grafts. When I wish to support a neighboring joint surface, as in the region of the knee, I employ thick sections of the tibia as struts, after which multiple shavings of bone are used to fill in the interspaces. Blood coagulates rapidly about such a mass of living bone and the most favorable conditions exist for the formation of new bone.

Indeed, in cases in which operation is performed properly the rapidity of the filling in of these defects has been astounding.

Although it is a technic employed more often in recent years, 21, or 17 per cent, of the patients in our

Fig 1—*a*, lateral view showing giant cell tumor of distal end of left radius (one year's duration), which was taken on June 8, 1937, eight months after curettage elsewhere; *b*, anteroposterior view, *c*, twenty six months after irradiation; *d*, anteroposterior view

series had excision and bone grafting. Of those who had benign lesions, 10 were operated on five or more years before this study was made; 9 of these were traced and 8, or 88.9 per cent, had lived five or more years. One of the 9 traced patients died of enteritis twenty-one months after operation. One patient that was not traced for as long as five years after operation was known to be well forty-two months after operation.

Fig 2—*a*, lateral view showing giant-cell tumor of lower end of the left tibia, *b*, anteroposterior view showing the tumor with involvement of the ankle joint

EXCISION, BONE GRAFTING AND IRRADIATION

In a group of 6 cases, or 5 per cent, irradiation was given after excision and bone grafting. In 5 of these operation was performed more than five years before

this study was made. Three patients were traced and all of them had lived five years. None of these had malignant lesions. Excision and bone grafting with or without irradiation result in the saving of extremities in cases which in former decades were considered hopeless, with amputation the only method of choice.

RESECTION

Resection of the entire portion of bone containing the tumor has a very limited field, but in certain cases in which there is involvement such as that found in the ribs, radius, ulna and fibula it is a method of choice. Certainly in those cases in which the tumor is located in the bone and the bone can be resected readily, such operation in the benign and low degree malignant type is ideal and should give the most satisfactory result. Simmons has reported good results in 100 per cent of

Fig 3—*a*, anteroposterior view showing giant cell tumor of the left ileum, *b*, anteroposterior view three years after biopsy and irradiation, which shows calcification of the tumor, *c*, same as *b* (lateral view).

his cases from the Registry of Bone Sarcoma. In our series 3 patients were operated on and traced and were living five years later (100 per cent).

AMPUTATION

Amputation was performed in 27, or 21.8 per cent, of our cases. In 24 of these amputation had been performed five or more years before the date of this study. All 13 patients who had had amputation for benign giant-cell tumor were traced for five years after operation and were well; 11 patients who had had amputation for malignant giant-cell sarcoma were traced for five years after operation; 8 of these survived for five years. Of the entire group of 24 patients on whom amputation had been performed five or more years before the date of this study, 21, or 87.5 per cent, survived for five or more years. In 20 of the

total 27 cases the amputation was a primary procedure, in 5 it followed excision and in 2 it followed bone grafting. Some of the patients had had previous treatment and were operated on a number of years ago, and infection, actinodermatitis, ulceration, fracture or recurrence may have been a complicating factor with or without malignant lesions. Amputation at that time was deemed advisable. Irradiation was not used prior to 1920 in our series, and of the 32 patients seen in the ten year period from 1916 to 1925 inclusive only 3 received irradiation, while during that same time amputation was performed in 13 cases. During the next fifteen years, from 1926 to 1940 inclusive, of the 92 patients seen only 14 had amputation while 20 had irradiation. Among older patients who have extensive destruction of bone in the region of a weight bearing joint, amputation may be preferred, whereas among younger patients an operation and attempt to save the extremity would

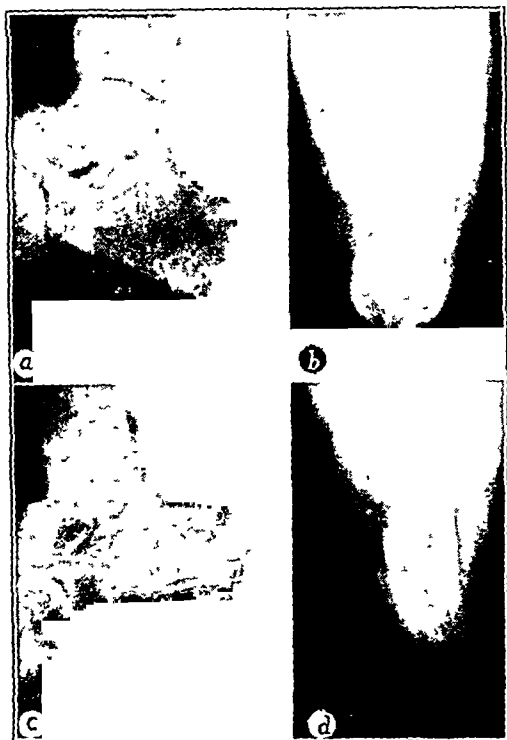

Fig. 4.—a, lateral view of the right foot showing giant cell tumor with extensive involvement of the os calcis, b, posterior view of the os calcis; c, postoperative lateral view showing multiple bone grafts in position after excision of the tumor, d, posterior view of os calcis showing bone grafts in position

be considered. In some instances in which we have amputated a painful and disabling extremity, the patient has been able to return to a gainful occupation with a complete change of his mental and physical condition.

Thirteen patients, or 65 per cent, of 20 patients who had malignant lesions, all of whom were operated on five or more years before the date of this study and traced, lived five years. Sixty-one, or 97 per cent, of 63 patients who had benign lesions and who were traced five or more years after treatment survived five or more years (table 6).

REPORT OF CASES

CASE 1.—A married woman aged 22, admitted to the clinic on May 10, 1937, complained of pain, local heat and swelling of the left wrist. She gave a history of having had a curettage of a tumor of the lower end of the left radius followed by eight roentgen treatments about nine months prior to her

admission. She denied trauma and stated that her symptoms had begun about one year previously.

A diagnosis of benign giant-cell tumor of the left radius was made, and after five courses of low voltage roentgen treatment the tumor was destroyed. In May 1941 the patient reported that, although some deformity was present, she had

Fig. 5.—a, lateral view showing malignant giant cell sarcoma of lower end of right femur, b, anteroposterior view showing destruction of lateral condyle of right femur.

had no recurrence of the tumor and had had no further treatment. Roentgenograms now showed that the tumor was completely calcified (fig. 1).

CASE 2.—A man aged 37, admitted to the clinic on June 26, 1939, stated that he had received an injury to the left ankle three and a half months prior to his admission, and two weeks

Fig. 6.—a, lateral view showing giant cell tumor of the upper end of right tibia; b, anteroposterior view; c, postoperative lateral view after excision of tumor and insertion of multiple bone chips; d, postoperative anteroposterior view.

subsequently pain and swelling had developed which had persisted. Furthermore he stated that he had consulted physicians, who had advised him to have his leg amputated for a malignant lesion

At the time of our examination there was pain and swelling of the left ankle and we suspected a malignant lesion but

advised operation under tourniquet and microscopic diagnosis. On June 27, 1939 the tumor was excised and bone grafts were inserted to fill in the defect. The pathologist reported a benign foreign body giant-cell tumor. Two low voltage roentgen treatments were given. Two years later, at the time of writing of this paper, the patient reported that he was well and had had no signs of recurrence of the tumor (fig. 2).

CASE 3.—A married woman aged 26, admitted to the clinic on June 8, 1937, complained of pain and swelling in the left buttock of four months' duration.

We suspected a malignant lesion of the left ilium, and an exploratory operation was advised. On June 16, 1937 the tumor was explored and on examination of the tissue the pathologist found that it was a benign foreign body giant-cell tumor. The patient was given nine low voltage roentgen treatments postoperatively and the tumor calcified.

In January 1941 the patient was delivered of a normal baby. At the time of writing of this paper, four years after institution of treatment, the tumor was completely calcified and the patient was in good health (fig. 3).

Fig. 7.—a, anteroposterior view showing giant-cell tumor with pathologic fracture of lower part of left tibia; b, lateral view; c, postoperative view showing fracture reduced and held by Parham bands, tumor excised and bone chips in position.

CASE 4.—A married woman aged 42, admitted to the clinic on Oct. 17, 1939, complained of pain in the right heel; there was no history of trauma.

A preoperative diagnosis of cyst or giant-cell tumor of the right os calcis was made. Operation was carried out on Nov. 1, 1939. A cystic cavity containing fluid and granulation-like tissue was removed; the pathologist reported a benign foreign body giant-cell tumor. The wound was swabbed with iodine, and multiple bone chips from the right tibia were inserted. The convalescence was uneventful and the patient reported seventeen months later that she was well and working and had had no further symptoms (fig. 4).

CASE 5.—A nun aged 40 years reported at the clinic for examination on Dec. 17, 1937, at which time she complained of pain and swelling in the lower part of the right femur of three months' duration.

A preoperative diagnosis of sarcoma of the right femur was made. Operation was performed on Dec. 20, 1937 under tourniquet, and an immediate microscopic diagnosis of malignant giant-cell sarcoma was made. The right leg was amputated immediately through the middle third of the thigh. The patient was given four low voltage roentgen treatments postoperatively. The convalescence was uneventful and, at the time of writing of this paper, the patient had had no recurrence and was well (fig. 5).

CASE 6.—A married woman aged 27, seen at the clinic on Dec. 19, 1939, complained of pain and swelling in the distal end of the right thigh of three months' duration.

A preoperative diagnosis of giant-cell tumor of the upper third of the right tibia was made. On Jan. 30, 1940 the tumor was excised and bone grafts were inserted. The pathologist reported a foreign body giant-cell tumor. The convalescence was uneventful, and one year after operation the patient was walking and apparently well (fig. 6).

CASE 7.—A boy aged 13 years, admitted to the clinic on Nov. 8, 1940, complained of pain, swelling and local heat in the lower part of the left tibia of two weeks' duration and stated that he had sustained a single severe injury at the site. A diagnosis of fracture of the lower part of the left tibia with questionable sarcoma had been made elsewhere.

A clinical diagnosis of giant-cell tumor or cyst with pathologic fracture was made. Operation was performed on Nov. 11, 1940, at which time the cavity was thoroughly excised. It was filled with yellowish granulation-like tissue, which was reported by the pathologist as a benign foreign body giant-cell tumor. The fracture was reduced and Parham bands were applied, after which multiple bone chips from the upper portion of the same tibia were packed about the region, completely filling the cavity. The convalescence was uneventful and the patient returned for observation two and a half months later, at which time the Parham bands were removed. The result was excellent (fig. 7).

SUMMARY

Giant-cell tumors may be divided into two groups, the benign giant-cell tumor and the malignant giant-cell sarcoma. These two terms clarify the question of the true nature of the lesion.

Accurate diagnosis and differentiation of benignancy and malignancy require microscopic examination and interpretation of the findings by a competent pathologist.

In tumors that apparently are benign, malignant changes may develop in time after surgical procedures or irradiation, or after a long period.

Treatment of the lesion varies in the individual case, but surgical removal when possible offers a rapid cure and permits an accurate microscopic diagnosis to be made in the majority of cases.

Irradiation has become of increasing value and may be used alone in some cases or as a postoperative adjunct.

The five year survival rate of patients with benign giant-cell tumor who are seen and treated early is 97 per cent, whereas for patients with malignant giant-cell sarcoma it is 65 per cent. The survival rate will be higher when all patients are seen early and the treatment is carried out by those who have had extensive experience with the condition.

The roentgenographic examination gives valuable information as to the location, size and character of the lesion, and the presence of pulmonary metastasis.

ABSTRACT OF DISCUSSION

DR. THEODORE A. WILLIS, Cleveland: My interest in the giant-cell tumor was aroused twenty-two years ago when as a house officer I had the privilege of working in the services of the late Drs. William B. Coley and George Barry. Dr. Coley called these things giant-cell sarcoma and treated them with his bacterial toxins. He reported a number of cures. Dr. Barry, in the other service, was convinced that they were benign. He called them hemorrhagic osteomyelitis and treated them by curettage, by swabbing with phenol and alcohol and by closure. Watching these two men and hearing their arguments back and forth, I became convinced that there were different types of this lesion: that they weren't all malignant and weren't all benign. Soon I had my first personal experience with one. The patient was a young man who had the lesion in the upper end of the radius. I curetted it, swabbed it with

phenol and alcohol and sewed it up. Pathologists at the University Hospital in Cleveland and at the Walter Reed Hospital reported the material a benign giant-cell tumor. Months later the patient came back with a recurrence. I excised the entire upper end of the radius, and he was given radium therapy by a competent radiologist. The pathologic report from that specimen was "osteofibroma; no signs of malignancy." A year later the patient came back again with a recurrence. We amputated his arm. The material went to the same two pathologists and both reported malignant sarcoma and both said that it was the type which did not tend to metastasize. That patient lived several years to my knowledge. He has left the city and I do not know whether or not he is alive, but that same lesion went through these three forms, so reported by competent pathologists. I have been confused at times by the way these things react. The epiphyseal type has reacted nicely to roentgen treatment in a number of cases. I am convinced, as Dr. Meyerding pointed out, that there are two types of these so-called giant-cell lesions, one of which is perfectly benign and responds well to thorough curettage and swabbing, and the other, which does not respond to that sort of treatment and does not even respond in my experience to roentgen or to radium therapy.

THE PROGNOSIS OF ACUTE HEMORRHAGIC NEPHRITIS IN CHILDHOOD

GEORGE E. PITTINOS, M.D.

STATEN ISLAND, N. Y.

JOHN DORSEY CRAIG, M.D.

AND

ADOLPH G. DESANCTIS, M.D.

NEW YORK

Various divergent opinions of the prognosis of acute hemorrhagic nephritis in children have been explained on geographic regional variations, variations in the general health of the individual at and after the acute attack, different interpretations of observations, and many other bases. Until the obvious procedure of establishing minimum criteria for a healed kidney is utilized and is used uniformly in all studies, this controversy will continue.

Great variations in the evaluation of the prognosis of nephritis do occur when different investigators apply different standards of normalcy. The criteria used in previous studies fall generally into three groups (*a*) those which employ physical examinations, blood pressures and routine urinalysis¹ (table 1), (*b*) those which include one or more renal function tests² (table 2), and (*c*) those which include the quantitative examination of concentrated urine (Addis count³) with renal

function tests done as a routine or whenever indicated* (table 3). Snoke⁵ was the only worker to use the Addis count repeatedly over an extended period of time (table 4) in addition to the aforementioned procedures.

From 1928 to 1939 there were 110 patients with acute hemorrhagic nephritis in the Post-Graduate Hospital. Four patients (3.6 per cent) died during the initial manifestation of their disease. An attempt was made to contact the remaining patients and have them return for a follow-up study. Thirty-two did return, and these comprise the material for this study. They were subjected to the following procedures: physical examination, blood pressure determination, complete blood count, routine urinalysis and an Addis count, chemical blood examination for urea, nonprotein nitrogen, creatinine, cholesterol, serum albumin and serum globulin, and a urea clearance test.

The group included 19 boys and 13 girls whose ages varied between 3½ and 15½ years. The period of time that had elapsed since the acute manifestation ranged from one to ten and one-half years, with an average of five and four-tenths years. Only 4 patients in the study had had the acute illness less than two years before being examined. This is of considerable importance, since a study of this type should not include any patient having had the acute attack less than one year previously, and it is well known that there may be residual renal changes which will clear entirely before the first year has elapsed.

PHYSICAL EXAMINATION

The physical abnormalities of our patients consisted of dental caries in 2 and soft systolic murmurs at the apex which were considered functional in 5. In the latter group the pulse rate was normal and no cardiac enlargement was present. Since none of these patients had cardiac complications during the acute attack, we feel that this finding has no significance in this study. Even patients who do show clinical evidence of cardiac involvement and failure during the acute attack, though adding immediate danger to life, have a good ultimate prognosis. In a study of 12 such patients, Rubin and Rapoport⁶ reported that only 1 showed residual cardiac damage.

BLOOD PRESSURE

Three patients aged 4, 5½ and 8 years respectively showed slight elevation in the systolic pressure. When these readings were rechecked eight months later, the 8 year old child had a blood pressure reading 118 systolic and 70 diastolic. The pressures of the other 2 were normal. Because the blood chemistry, urea clearance and Addis counts were all normal, this hypertension probably has no significance. Hypertension usually closely parallels increases in blood urea and nonprotein nitrogen and is of value mainly in the late latent and terminal stages. We, however, intend to keep the child with the hypertension under observation.

BLOOD COUNTS

Only 1 patient showed any evidence of anemia. This was a 3½ year old child with 3,740,000 red blood cells and a hemoglobin reading of 9.8 Gm. There was no

other abnormal finding, and it probably bears no relation to the original nephritis. Presumptive evidence of this lies in the fact that Brown and Roth⁷ and Ashe⁸ have shown that the anemia in nephritis is directly proportional in intensity to the degree of impairment of renal function, of which this child had none.

TABLE 1.—Criteria Employing Physical Examinations, Blood Pressures and Routine Urinalysis

	Number of Cases	Time Observed	Healed	Abnormalities	Comment
Schwarz et al . . .	120	1 to 16 years	101 (84 1%)	14 (11.7%)	5 had albuminuria only (4.2%)
Osman	56	1½ to 22 years	36 (64%)	20 (36%)	5 had elevated blood pressures only
Boyd	44	2 to 5 years	36 (82.8%)	8 (17.2%)	Albuminuria with or without casts
Paterson	26	3½ to 5½ years	12 (47.5%)	14 (52.5%)	9 of these had urinary abnormalities only
Lyttle	38	1 to 7 years	34 (89.4%)	4 (10.6%)	

URINALYSIS

The urine of 2 patients showed faint traces of albumin, of 2 showed traces and of 2 showed 1 plus albumin. Of the 2 who showed faint traces, 1 had a high white blood cell count in the Addis count with no other abnormality, and the other showed the same conditions plus a chronic genitourinary infection, with an intravenous urogram showing bifurcation of the renal pelvis on the left side. We believe that the albuminuria in both of these cases was due to the pyuria and not to nephritis.

TABLE 2.—Criteria Including One or More Renal Function Tests

	No of Cases	Time Observed	Healed	Abnormalities	Function Test Used	Comment
James	67	3 mo to 16 yrs.	58 (86%)	9 (14%)	Specific gravity concentration test	Considered only albuminuria significant
Guild	34	1 to 12 yrs	9 cases of albuminuria only—failed to classify		Phenolsulfonphthalein 2 hr renal function test; nonprotein nitrogen	
Tallerman	16	8 yrs	15 (93.4%)	1 (6.6%)	Blood urea phenolsulfonphthalein; urea concentration	Includes in recovery albuminuria but no casts or abnormal cells
Smellie	16	Average 16 yrs.	5 (33%)	11 (66%)		Had either high blood urea and low urea concentration test or enlarged heart and raised blood pressure; urines all normal

The 2 patients showing traces of albumin were reexamined this month and urinalyses, including Addis counts, gave negative results. One patient having 1 plus albumin showed no other abnormality, and we were unable to get this child to return for reexamination.

7. Brown, G. E., and Roth, Grace M.: The Anaemia of Chronic Nephritis, *Arch. Int. Med.* 30: 817 (Dec.) 1922.

8. Ashe, Benjamin: The Hemoglobin Percentage and the Red Blood Cell Count in Bright's Disease, Myocardial Insufficiency and Hypertension, *Arch. Int. Med.* 44: 506 (Oct.) 1929

He will have to be followed further before his condition can be classified and until then must be considered as having potential latent nephritis. The other child having 1 plus albumin was recently reexamined and found to have only a faint trace. With all other conditions normal and with the Addis count, including a quantitative estimation of the protein content (0.18 Gm.) within normal limits, we do not believe that this child should be classified as having persistent nephritis.

Persistent albuminuria unaccompanied by any other abnormal finding is, in a study of this type, hard to interpret. The interpretations vary from Guild's² liberal feeling that albumin may stay in the urine for years with no damage to the kidney, to the more conservative attitude of Snook⁵ and Schwarz and his associates¹ that children must be further observed and have normal urine before being given a clean bill of health. We agree with the latter opinion. Depending on the interpretation of this finding, evaluation of the prognosis of any series of nephritic patients may be good or extremely bad.

RENAL FUNCTION TESTS

Mosenthal⁹ has wisely observed that no one particular test really deserves preference, but a full realization of the significance of these tests will come only to the

TABLE 3.—Criteria Including Addis Count

	No of Cases	Time Observed	Healed	Abnormalities	Comment
Cass	85	6 mo to 5 yrs	56 (66%)	29 (33%)	2 patients in terminal stage of disease
Boyle et al	25	6 mo. to 8 yrs	25 (100%)	..	Patients selected from a series of 250 clinically healed postinfectious nephritides; 1 had a high Addis count, with chronic infection of the urinary tract

physician who has carried out and read many observations and has become familiar with them and their many variations. Other investigators have used singly or in combination the phenolsulfonphthalein test, the two hour concentration test, various clearance tests and blood chemistry studies. We used the urea clearance test, since we agree with Mosenthal¹⁰ and Lyttle¹¹ that it is probably the most accurate way of determining the functioning kidney tissue, and we rechecked these observations with blood chemistry studies to see how efficiently the available kidney parenchyma was eliminating the renal excretory products.

Van Slyke¹² has shown that the concentration test is more sensitive than the clearance test to slight degrees of renal damage; hence if the concentration test yields a normal result, it is not necessary to measure the clearance. On the other hand, he has shown that the concentration test fails to show the differences between moderate and severe renal damage. If the concentration test yields a urine of low specific gravity, it is necessary to determine also the urea clearance in order to ascertain whether the decrease in excreting power is serious.

11. Lyttle, V. D., in Holt, L. E., Jr., and McIntosh, Rustin: *Heli's Diseases of Infancy and Childhood*, ed. 11, D. Appleton Century Company, Inc., 1939, p. 790.
12. Van Slyke, D. D.: *Renal Function Tests*, New York State J. Med. 41: 825 (April 15) 1941.

The urea clearance test is especially important since it is recognized¹³ that the usual tests for renal function indicate impairment only when from 50 to 60 per cent of the kidney tissue is not functioning.

In all 32 cases we found normal urea clearance and no abnormalities in the chemistry of the blood. This is of special significance, since it is associated with the following Addis counts.

TABLE 4.—*Snoke's Results*

Snoke	From 1920 to 1936—154 patients followed—29 of them for less than two years.
	57 (37%) cured; 33 (21%) died and 64 (42%) still had active nephritis (California).
	Working in Rochester, N. Y., finds only approximately 10 per cent with persistence of urinary changes.

ADDIS COUNT

Snoke⁵ has shown that during the latent period of nephritis the child may be in apparent good health and the ordinary renal function tests may indicate normal renal function. He has further shown that in these children a latent nephritis may exist and be revealed only by the quantitative study of concentrated urine (Addis count).

Cass,⁴ in her study using the Addis count, showed that 16 patients were actually in the latent stage but clinically were normal and had normal urine on routine examination. Eleven of these even gave normal Addis readings one or more times, and she agrees with Snoke that these counts should be done repeatedly. Boyle and his associates⁴ selected 25 patients from 250 clinically healed patients with postinfectious (hemorrhagic) nephritis, and did one Addis count on each. All were normal except one who had a chronic infection of the renal tract.

The contradictory results in these various studies (tables 3 and 4) in which the Addis count was used are probably due partially to the fact that the counts were not repeated over a given period of observation as was done by Snoke. Originally we did one Addis count on each of our 32 patients. As a criterion of normalcy we used the ranges established by Lyttle¹⁴ and Snoke¹⁵ (table 5).

TABLE 5.—*Ranges of Addis Counts of Lyttle and Snoke*

		Average	Min- imum	Maxi- mum	Suggested Super- normal
Casts.	Lyttle	1,085	0	12,916	10,000
	Snoke	1,230	0	29,000	10,000
White epithelial cells.	Lyttle	322,184	9,000	2,822,000	2,000,000
	Snoke
Red blood cells.	Lyttle	15,181	0	129,000	600,000
	Snoke	81,600	0	800,000	600,000
Protein (albumin), mg.	Lyttle	18.5	3	47	35
	Snoke	28.5	5	90	55

All of our patients had a normal reading except 2 who had high white blood cell counts. Twenty patients had no red blood cells; the other 12 had red cells ranging from 14,333 to 172,000. None had any casts. The two high white counts were 19 and 20 million respectively, and both patients had a faint trace of albumin with no other abnormality in the routine urinalysis. One patient,

as we stated before in discussing urinalysis, had a chronic infection of the urinary tract with a bifurcation of the left renal pelvis. This can account for the high white cell count. The other patient had an accompanying albuminuria, with all other examinations negative, and we feel that this patient has pyuria rather than nephritis. Three of the original 6 patients with albuminuria were reexamined with a second Addis count, all of which were within normal limits.

The use of the Addis technic is impracticable in routine urinalysis but should be employed when the slightest urinary abnormality exists and should be repeatedly done whenever this abnormality persists. It should be a prerequisite before the discharge of a nephritic patient when all other conditions are normal.

SUMMARY

Thirty-two children who had acute hemorrhagic nephritis were studied from one to twelve years after the acute attack. All were essentially normal physically except 1 who had an elevated blood pressure. Routine urinalyses showed originally 6 with albuminuria. Two of these had high white blood cell counts in the Addis readings, which were ascribed to pyuria rather than to nephritis. Two were reexamined eight and ten months later and found to be normal. One patient showed no other abnormality and had two normal Addis counts eight months apart. We think that this patient should not be classified as one having latent nephritis. One patient having no other abnormality refused to return for further study and necessarily must be classed as having potential latent nephritis.

Chemical examinations of the blood for retention of nitrogenous products were all negative. Urea clearance tests on all patients were negative and there was no anemia ascribable to the nephritis.

Addis counts done on all the children were normal, with the exception that 2 had high white blood cell counts that we felt were due to pyuria rather than to nephritis.

No patients were in the terminal stage.

From the evidence in this study and from a review of the literature on this subject it is evident that minimum criteria should be established for a normal kidney before a patient is discharged as cured after an acute attack of hemorrhagic nephritis, and we suggest the following: routine physical examination, blood pressure and urinalysis every three months up to and including two years after the acute attack, and an Addis count done at this time. If during the course of these two years there is the slightest urinary abnormality, the case should be followed at intervals with Addis counts and urinary function tests as indicated. All scientific studies should include the Addis count in following the course of the disease.

Although the evidence we have correlated from this study gives an excellent prognosis to acute hemorrhagic nephritis in this group of children who survived the initial attack, we feel that the outcome of any one case or group of cases is unpredictable.

CONCLUSIONS

1. Of 32 cases of acute hemorrhagic nephritis followed and studied for from one to twelve years after the acute attack, only 1 is possibly in the latent stage of nephritis and none is in the terminal stage.

2. The investigatory work on the prognosis of nephritis should be standardized on the suggested minimum criteria for a healed kidney so that results in various studies may be compared intelligently.

ABSTRACT OF DISCUSSION

DR. JEROME L. KOHN, New York: Drs. Schwarz, Weiner and I have followed at the Mount Sinai Hospital about 230 patients discharged from the pediatric service with a diagnosis of acute hemorrhagic nephritis. These patients were followed from one to twenty years after the onset, the average period of study being four to five years. Of all our patients with acute nephritis 5 per cent died, usually in the first week of illness. Of the patients followed, about 85 per cent seemed to have recovered completely. Of the remaining 15 per cent, slowly progressive chronic nephritis had developed in 5 per cent. Another 5 per cent had what we call nonprogressive nephritis; that is, there was constantly some albuminuria, perhaps slight hypertension but no clinical symptoms. This group has been followed from one to seven years. The remaining 5 per cent we have as yet not classified. Except for occasional albuminuria, they are clinically normal. We have noted what we call the "illness test." By this we mean how well does the kidney withstand infection after an apparent recovery from acute nephritis? During such an illness some children have slight albuminuria and a few red blood cells in the urine. We consider their nephritis as probably not completely healed. If a patient does not have albuminuria, hypertension or an increase in blood urea for one year after the onset there is probably a complete cure. We believe that intensive urinary functional tests are not necessary to give a satisfactory prognosis except in the occasional case in which the prognosis is difficult or when the patient cannot be adequately observed clinically for a long enough period. There are few records of postmortem examination of persons who have had acute hemorrhagic nephritis and died of another illness several years later.

EMBRYOMA OF THE KIDNEY
(WILMS' TUMOR)

WILLIAM E. LADD, M.D.

Professor of Child Surgery, Harvard Medical School; Chief of
Surgical Service, Children's Hospital

AND

ROBERT R. WHITE, M.D.

Assistant in Surgery, Harvard Medical School; Resident Surgeon,
Children's Hospital

BOSTON

Embryoma of the kidney has been classified under various titles according to the predominant cell found at microscopic examination. For this reason it is important to define clearly what is meant by this term. We consider embryoma of the kidney as a highly malignant tumor peculiar to infancy and early childhood. It originates in the kidney and is of probable congenital origin. The tumor grows rapidly at times and assumes enormous proportions. Metastasis takes place by direct extension through its capsule, by the regional lymphatics or by the blood stream to the lung or brain. On gross appearance the tumor is a large encapsulated, grayish white mass encroaching on some portion of the kidney and destroying a greater or lesser part of it by pressure. The remaining portion of the kidney is divided from the tumor by a connective tissue capsule, but it cannot be dissected free from it. Occasionally, malignant nodules are found in this separated portion of the kidney. On microscopic examination one finds the tumor made up of undifferentiated or partially differentiated cells of the epithelial or connective tissue group. One may find in the same tumor epithelial cells, smooth and striated

muscle cells and even bone or cartilage. There may be a great variation not only in the cells but also in the degree of activity in various portions of the same tumor. Hemorrhage and necrosis within the tumor sometimes leading to rupture of the capsule are not uncommon, and invasion of the renal vein or renal pelvis also occurs. As the predominance of one type of cell over another has no bearing on the progress of the tumor or the prognosis for the child, the subdivision of these tumors according to the predominant type of cell can serve no useful purpose clinically.

The renal embryoma should be differentiated from the sympathetic neuroblastoma arising either in the medulla of the adrenal or in the retroperitoneal space adjacent to it or rarely in the kidney itself. The neuroblastoma has a different gross and microscopic appearance and the metastasis commonly takes place earlier and to bone rather than to the lung. The hypernephroma or Grawitz tumor occurs so rarely in early childhood that it should not be a source of confusion. We have not seen a tumor of this type in a child under 12 years of age. The one other tumor which might cause difficulty in differentiation is the embryoma of renal anlage which resembles closely the embryoma of the kidney, both grossly and microscopically, but it is not attached to the kidney.

DIAGNOSIS

In the diagnosis of embryoma of the kidney the age incidence is of some significance, as this tumor is primarily a disease of the first three years of life. Our youngest patient was 2 months old and the oldest was 9 years, the average being between the second and third years. The distribution between the two sexes and between the two sides is so nearly equal that it is unimportant. The correct diagnosis is arrived at largely from the clinical history and from palpation of the abdomen, and to a lesser degree by supporting evidence of roentgen examination.

The commonest complaint of the parent or child is swelling of the abdomen and not infrequently the feeling of the mass. Occasionally the child shows loss of weight but more commonly the child remains in an excellent state of nutrition, even in the presence of an enormous tumor. From pressure on adjacent organs these children sometimes have vomiting, abdominal pain, anorexia, irritability or listlessness, but such symptoms are more commonly absent.

On physical examination the tumor can usually be moderately accurately outlined as it is not tender and there is no muscle spasm over it. It feels solid, is not mobile and usually has a smooth and rounded outline extending often to the midline and from the costal border well down into the ileac fossa. Although gross or microscopic hematuria is not an uncommon finding, it is not frequent enough to be in any sense pathognomonic and, in fact, normal urinary conditions are more usual.

Pyelography may and, as a rule, should be used as an aid to diagnosis, but there is no distortion of the renal pelvis sufficiently characteristic to be positively indicative of embryoma. In an embryoma of the kidney the renal pelvis is commonly displaced upward or downward according to the position of the tumor, and it is sometimes pushed toward the midline. In a retroperitoneal neuroblastoma the pelvis may be displaced laterally, but there is not enough uniformity in either of these conditions to be able to differentiate the two by the pyelogram alone. Of course if one cannot differ-

From the Surgical Service of the Children's Hospital and Department of Surgery, Harvard Medical School.

In the preparation of this paper one hundred and sixteen articles on Wilms' tumor were reviewed. Only those articles quoted in the text are mentioned.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 3, 1941.

entiate between the new growth of the kidney and hydronephrosis or pyelonephrosis, the pyelogram will settle the question. The real merit in pyelography in a case of suspected embryoma, however, is to determine the presence and normality of the kidney of the opposite side. Since embryomas occur most commonly in the age group requiring a general anesthetic for retrograde pyelography, we are commonly satisfied with the data obtained by the intravenous method. By using this method and avoiding a general anesthetic, less delay is occasioned than by a cystoscopic examination. It is of paramount importance to make the diagnosis of embryoma as early in life as possible, as from our experience the younger the patient the better is the chance of cure. The number of cures that we can anticipate in the future is therefore dependent to some extent

Fig 1 (A. R.).—Section under low power magnification showing typical appearance of an embryoma of the kidney. The specimen was taken for biopsy from a mass involving the right kidney, Jan 27, 1938 of a patient with bilateral embryoma.

on the alertness of the pediatrician and of the family physician and their realization of the existence of this extremely malignant tumor of early life.

We abandoned the practice of aspiration biopsy many years ago. It is unreliable and may cause implantation recurrence or set cells loose into the blood stream to result in remote metastasis. The danger of malignant cells entering the blood stream is a real one, and every precaution should be taken to avoid its occurrence. On a theoretical basis rough or frequent palpation of the tumor is contraindicated.

Other intra-abdominal tumors that occur in this age group are ovarian tumors, splenomegaly, omental cysts, duplications of the alimentary tract and new growth of the liver, but they all have characteristics sufficiently definite to make their differentiation possible.

PREOPERATIVE IRRADIATION

There is no uniformity of opinion about the merits of preoperative irradiation, although its employment has been widely advocated. The advantages and disadvantages of this form of therapy should be carefully con-

sidered. Almost all surgeons and roentgenologists are agreed that this tumor is usually quite radiosensitive, that its size may be diminished by a comparatively short course of roentgen therapy and that the operative procedure may be somewhat facilitated thereby. Also, prac-

Fig 2 (A. R.).—Same specimen as shown in figure 1 under high power magnification.

tically all surgeons and pathologists are agreed that no case of proved embryoma has been cured by roentgen therapy. In every specimen that has been examined following roentgen therapy viable cells have been in evidence.

Does roentgen therapy hinder or prevent metastases? There is no evidence that it does. In fact, on a theo-

Fig. 3 (A. R.).—Specimen of same kidney and tumor outside kidney shown in figures 1 and 2 removed at autopsy Sept 5, 1938 after 9,600 roentgens had been given in radiation therapy. Viable tumor cells are still present.

retical basis it might facilitate rather than hinder metastasis. It is known that the effect of irradiation is first to soften the tumor and then to contract it by the replacement of some of the cellular elements with connective or scar tissue. During this period of change it

would seem at least logical to presume that malignant cells might enter the blood stream quite as easily, if not more easily, than if the changing process had not been caused by the roentgen treatment. Regardless of the accuracy or inaccuracy of this theoretical conjecture, we will defy anybody to prognosticate when metastasis is going to take place. In instances in which patients have died of remote metastasis and have shown no local metastasis at postmortem examination it is fair to assume that the metastasis had taken place prior to operation and that the child's life might have been saved had the operation been performed a month, a week or even a day earlier. In some instances we actually have found tumor cells floating in the blood stream of the renal vein at the time of operation. In instances in which the patients have been cured, presumably the operation was performed before metastasis had taken

high, in recent years this situation has been changed. In the days when we attempted these operations by the posterolumbar incision, when knowledge of fluid balance was limited and when the use of transfusion was only occasional, our operative mortality was very high. In the last eight years, however, with the adoption of the transperitoneal approach and with improved technic in preoperative and postoperative treatment, we have performed 23 nephrectomies for renal embryoma with no operative mortality. The last operative death occurred in 1932. We define operative mortality as any death which takes place while the patient is in the hospital.

OPERATIVE TECHNIC

Perhaps the most important feature of the operative technic is that it should be done as soon as a probable diagnosis can be made and the patient properly pre-

place. If the foregoing statements are correct, one would expect to find that more patients with embryoma have been cured without the use of preoperative roentgen therapy than with it.

In a very extensive review of the literature we have found 563 cases reported with 26 cures in which it was specifically stated whether or not preoperative roentgen therapy had been used. Of these only 8 patients had received preoperative roentgen treatment. In our own series the contrast is even more striking—only 1 of 14 patients with probable cure had received preoperative irradiation. From a statistical point of view, then, it can be stated that the chance of survival for a patient with embryoma of the kidney is far greater if the policy of immediate operation is adopted rather than the policy of delayed operation following roentgen therapy.

The only argument left in favor of employing preoperative irradiation is that the operative mortality is high and that this complimentary therapy reduces it. While it is true that in some other clinics, as well as in our own, in the past the operative mortality was

pared. Since a general anesthetic is indicated, we elect the use of ether. The transperitoneal approach has many advantages over the retroperitoneal approach through a posterolumbar incision. Whether this transperitoneal approach is done through a vertical or a transverse incision is immaterial except that in the common large

TABLE 2—Mortality in Wilms' Tumor The Children's Hospital Series

Operative mortality	23.0%	23.5%	10.0%

tumors—extending to or beyond the brim of the pelvis—the vertical incision is preferable. We usually use a vertical incision. After the anterior parietal peritoneum has been opened, the ascending or descending colon according to the side on which the tumor exists is packed toward the midline and an incision is next

made in the posterior peritoneum over the tumor or renal pedicle. The renal pedicle and ureter are next carefully exposed, tied and cut before any attempt is made to mobilize the tumor and attached kidney. We believe that doing this step in the operation first is

Fig. 4 (S S)—Section from a recurrent tumor which had been treated by roentgen rays, showing tumor cells embedded in a fibrous tissue background

of prime importance. It results in the loss of much less blood and minimizes the danger of pushing malignant cells into the blood stream in the process of handling the tumor. The tumor is next mobilized and removed with as much perirenal fat as possible, especially that about the renal pedicle, as this contains the lymphatics in which recurrence may take place. The large raw surface of the posterior abdominal wall is now covered over with peritoneum when feasible or disregarded if not feasible. The abdominal wound is next closed in layers without drainage. In the postoperative care morphine is given in adequate doses and parenteral fluids or transfusion given as indicated.

We abandoned the use of the posterolumbar incision many years ago for the following reasons: It is extremely difficult or even impossible to remove some of these tumors through such an incision. It is possible that some tumors are classed as inoperable because they are approached by this route. Since adopting the transperitoneal approach, we have not considered any case inoperable and have successfully operated in at least 1 case in which the weight of the tumor was one fourth that of the child. We think that more blood is apt to be lost when the tumor is approached by the posterolumbar route. When this incision is used, the kidney must be handled before the renal pedicle is tied and the possibility of spreading malignant cells into the blood stream must be increased. We believe that our lack of mortality in the last eight years is due largely to adopting the transperitoneal approach and to the increased facility which this approach gives in handling the renal pedicle and in removing the tumor.

POSTOPERATIVE IRRADIATION

The difficulty in evaluating the merits of postoperative irradiation is even more appreciable than that of evaluating the merits of preoperative irradiation. We have been unable to find in the literature a sufficient number of cases in which it was stated that postoperative irradiation had been used to make the numbers of any statistical significance. Our own experience with this form of therapy has also been too limited to be of much value. We can state, however, that roentgen therapy on a recurrence apparently has a similar reaction to that on the original tumor, namely that it shrinks the tumor but does not destroy all the cells. All specimens of a recurrent tumor that have been irradiated and later have been examined have shown viable cells. We have no patient who has had a recurrence and who has survived. From this experience it would seem logical to deduce that one cannot cure a recurrent embryoma by roentgen therapy any better than one can cure the original tumor. One must, therefore, consider postoperative irradiation only from the point of view of prophylaxis against recurrence.

If one is going to use this form of therapy for this purpose, the most suitable parts of the anatomy to irradiate would be the abdomen, the lungs and the brain. It is doubtful whether sufficient doses of roentgen rays could be given to these areas so as to destroy at once the malignant cells which might have lodged there without giving so much that it would destroy the child. For the present it must be stated that there are insufficient data available to evaluate the merits of postoperative roentgen therapy and that if it is used

Fig. 5 (S. S.)—Same section shown in figure 4 under high power magnification. Note that viable and numerous striated muscle tumor cells are still present.

it is on the vague chance that it might destroy some cells which otherwise would grow to form a lethal recurrence. One might add that the use of postoperative roentgen therapy does not have the disadvantages of preoperative irradiation, namely delaying the operation beyond the time at which the cure may be obtained.

PROGNOSIS

The statement is commonly found in the literature that the mortality of embryoma of the kidney is between 90 and 100 per cent. From our extensive review of the literature, this estimate seems to be quite accurate as the mortality of the combined results of numerous clinics. Among the larger series that have been reported

Fig. 6.—Time of recurrence of Wilms' tumor (postoperative) in the Children's Hospital series.

recently may be mentioned those of Priestley¹ in 1939 with 37 cases and 4 cures, Campbell² in 1937 with 37 cases and 2 cures, Higgins and Shively³ in 1941 with 26 cases and 4 cures and Kretschmer⁴ in 1938 with 24 cases and 3 cures.

Our own series comprises 60 patients, 18 of whom are still living; 14 of these have probably been cured while 4 have been operated on too recently to be so classified. Of these 4 patients, 3 are considered as having a very hopeful prognosis and 1 as having a hopeless outlook, since there is a bilateral tumor.

Are there any factors in the particular case which give a clue as to the probability of recovery or cure? It is frequently stated that the size of the tumor bears a direct relation to the mortality. Our experience does not coincide with this statement, as some of our patients with the largest tumors are among those cured, while some of the patients with the smaller tumors have had early metastasis and a fatal outcome.

We have been unable to correlate any relationship between the predominant type of cell and the chance of cure. In our series there appears to be a relationship between the age of the patient and the curability.

TABLE 3.—Embryoma of the Kidney (Wilms' Tumor): The Children's Hospital Series

Total number of cases.....	60
Number of deaths.....	42
Operative.....	8
Metastases.....	32
Unrelated.....	2
Number of probable cures.....	14
Number of hopeful cases.....	3
Number of hopeless cases.....	1

Of 16 cases occurring in the first year of life, 50 per cent resulted in cure. Gross hematuria which occurred in 10 of our patients was a bad sign, as all the patients with this condition died. Also, the patients in whom the tumor had invaded the renal vein had a fatal result.

In the vast majority of cases recurrence is detectable by the end of four months so that if no evidence of recurrence or metastasis is demonstrable at this length of time we become hopeful about the ultimate result. Twenty months is the longest time that a patient has gone without showing signs of recurrence and then had it develop, and this happened in 1 instance only. In our series there were 32 recurrences; 31 of these took place prior to the ninth month after operation. We have had no patient who has gone for two years without recurrence in whom it has later developed. In this particular form of malignant tumor, therefore, it is reasonable to consider a patient as probably being cured who has survived for two years after operation without evidence of recurrence.

Table 4 shows the number of patients probably cured and the duration of their cure out of a series of 60 patients treated at the Boston Children's Hospital. The first 11 of the 14 probable cures listed in table 4 were previously reported by one of us.⁵

CONCLUSION

The results of a review of the literature and our experience lead us to conclude that in the treatment of embryoma of the kidney:

1. The operative mortality should be negligible.
2. The transperitoneal approach is safer and is to be preferred to the posterolumbar retroperitoneal approach.
3. If operation is performed as soon as the diagnosis is made, the chance of curing the patient is greater than if it is delayed until after roentgen therapy has been given.
4. Insufficient data are available to permit evaluation of the merits of postoperative roentgen therapy.

300 Longwood Avenue.

ABSTRACT OF DISCUSSION

DR. JAMES T. PRIESTLEY, Rochester, Minn.: The results which Drs. Ladd and White have reported are definitely superior to any others recorded in the literature. This fact in itself speaks for their methods of treatment. The important point discussed by the authors, concerning which divergent opinions exist, pertains to the value of irradiation in the treatment of Wilms' tumor. Drs. Ladd and White object to preoperative irradiation because metastasis might occur during administration of roentgen therapy. That preoperative irradiation does facilitate surgical removal of the tumor by decreasing

its size is a definite advantage to most surgeons. In order to determine what effect irradiation might have on ultimate results, a recent review has been made of all cases of Wilms' tumor in which nephrectomy was performed at the Mayo Clinic prior to 1937. This permits of a follow-up period of five years in order to determine end results. According to the experience of Drs. Ladd and White, a two year follow-up should provide adequate information in this regard. Although the number of cases in this series is too small to permit definite conclusions, some suggestive evidence with regard to the value of irradiation may be obtained. There were 39 patients in all, 6 of whom have survived five years or more after operation, a survival rate of 15 per cent for this period. There were 13 patients on whom nephrectomy alone was performed; 1 of these (8 per cent) survived five years or more. There were 3 patients for whom preoperative irradiation and nephrectomy were employed; not one of these is living at present. There were 11 patients for whom nephrectomy and postoperative irradiation were employed; 2 of these (18 per cent) have survived to the present time. There were 12 patients for whom preoperative irradiation followed by nephrectomy at an appropriate time and subsequently postoperative irradiation were employed; 3 of these (25 per cent) are still living. From this limited experience irradiation seems to enhance ultimate results when utilized in association with nephrectomy in the treatment of Wilms' tumor. It should be emphasized that irradiation alone without surgical intervention does not constitute adequate treatment for these lesions. Perhaps it would be well to compromise and utilize preoperative irradiation only when the tumor is so large when first examined that nephrectomy would be difficult or almost impossible. If a small Wilms' tumor, which unfortunately is seldom seen, should be encountered, perhaps one could proceed directly with nephrectomy. In all cases it seems advisable to me to use extensive postoperative irradiation.

DR. MONROE WOLF, New Orleans: The rarity of this condition in early childhood may be cited by presenting the incidence in two of New Orleans' largest hospitals, Charity Hospital and Touro Infirmary. At Touro Infirmary for the period January 1933 through April 1941 there was a total admission of 86,022 patients, 4 with Wilms' tumor, 2 each white males and white females. Two of these patients were apparently well three years after operation, an unusually high incidence of apparent cure. At Charity Hospital from July 1, 1937 until May 1, 1941 the total admission was 230,300 patients, of whom 6 had Wilms' tumor, 2 white male, 1 white female, 1 Negro male and 2 Negro females. Three of these patients were admitted during the past three months. There have been no three year survivals in this series. As a urologist I wish to impress the difficulty in differentiating these tumors from an extrarenal retroperitoneal new growth.

DR. WILLIAM E. LADD, Boston: Dr. Priestley apparently has in mind the danger that somebody will consider that the sole treatment for embryoma of the kidney is roentgen therapy, and I think he is wise in bringing that point to our attention. There is an added danger in this regard because it is sometimes difficult to differentiate between the retroperitoneal blastoma and the embryoma of the kidney. The neuroblastoma is rather a strange tumor; there are on record a certain number of cases of neuroblastoma that have been cured by roentgen therapy, and there are a few cases—Dr. Cushing reported 1 many years ago—that have regressed without any treatment. We have had 1 patient at Children's Hospital, and we have 5 or 6 more who are well after many years following roentgen therapy. But we would not give roentgen therapy without being sure of our diagnosis. I think it is a great mistake ever to give roentgen therapy for any of these abdominal tumors unless one knows what one is treating. Regarding the pyelograms that Dr. Wolf showed, we have a feeling that the neuroblastoma, the retroperitoneal blastoma, is a little bit more likely to push the renal pelvis laterally, whereas the embryoma is more apt to push it medially, upward or downward. There are enough exceptions so that I don't believe one can differentiate between the two by the pyelogram alone.

LEGAL AND THERAPEUTIC ASPECTS OF SYPHILIS AND PREGNANCY

CHARLES H. PECKHAM JR., M.D.

COOPERSTOWN, N. Y.

More than twenty-five years have elapsed since the first legal attempt was made to control the transmission of venereal disease from one partner in marriage to the other. This early legislation was faulty and failed to produce the desired result, since it did not apply to both sexes and did not require microscopic or serologic tests as aids in diagnosis. In the last five years the public has been made violently conscious of the venereal disease problem (and particularly so with regard to syphilis) both from the standpoint of the individual and from that of the community, the state and the nation as a whole. Partly because of this and partly because public health authorities have instituted an active anti-venereal disease campaign, many state legislatures have enacted statutes to forbid the issue of marriage licenses to persons suffering from such diseases unless it was felt that the condition is not communicable. As a natural corollary to this effort, laws have also been passed requiring that physicians perform a serologic test for syphilis on all pregnant women under their care. The first of the new premarital examination laws went into effect in Connecticut in 1936. At present thirty-one states have enacted some sort of similar legislation, while in twenty antepartum examination laws are in effect. It seems of particular interest that all this legislation has been passed chiefly through the efforts of lay organizations and that physicians, both individually and as a group, rarely have been consulted as to the content of the law or its probable effects. Indeed the subject has become one of considerable acrimonious debate among physicians and venereal disease authorities as well.

A brief discussion of the premarital examination laws may first be undertaken. These laws differ in many ways. Some require clinical and microscopic examinations in an effort to establish or rule out the presence of gonorrhea. Except when there are obvious signs and symptoms the diagnosis of this condition at the present time is so unreliable as to leave little to recommend its inclusion in a statute. A false positive diagnosis is made infrequently, and a true positive reaction is missed in the majority of cases. With syphilis the situation is considerably different. Examination by a licensed physician of both the prospective bride and the prospective groom, including serologic tests for syphilis, is required in twenty states. Four states require examination of the groom only. Six other states prohibit the marriage of persons with venereal disease, some of them requiring a personal affidavit as to freedom from infection but making no specification as to examination.

Obviously many premarital examination laws have been passed hastily and without due regard to the transmission of syphilis as it is understood by syphilologists. It follows that they not only will fail to attain the desired end but will render all such legislation, both present and future, unpopular with the public.

The American Social Hygiene Association, one of the most important agencies sponsoring legislation

governing premarital examination, recognizing the many defects in present statutes, has recently suggested a so-called ideal law.¹ This law, for reasons previously stated, is limited to syphilis. It requires that both applicants for a marriage license be examined for syphilis by a licensed physician. The examination should be both clinical and serologic, the serologic test being of a type approved by the state health department. The tests should be made not more than thirty days before the license is applied for, and the license when issued should be valid for not more than sixty days. The blood test should be done without charge on request through the local health department. The filing of a certificate by a physician and the laboratory statement may be waived by the judge of a proper court because of an emergency or for some other cause. With this rare exception, the physician must file a certificate of examination accompanied by the report of the laboratory test, which includes the name and the address of the applicant, the date and type of test but not the result. The result of

marize these briefly. Proponents of such legislation have advanced the following points:

1. Syphilis is frequently transmitted through marriage when one partner is infected. Frequently the diseased person is unaware of his or her infection. The vast majority of pregnant women found repeatedly to have a positive serologic reaction give a history completely negative for signs and symptoms of syphilis.
2. The most valuable single means of diagnosing syphilis, particularly as far as the general practitioner is concerned, is the serologic test.
3. Premarital blood tests will reduce the incidence of the transmission of syphilis to the spouse and to the children.
4. Untreated syphilis not infrequently results in the incapacitation or early death of one partner. Both partners should be aware of this possibility before marriage. If incapacitation results, support for the family may have to come from public funds, and thus the problem may become of interest to the state from the standpoint of relief. Furthermore, the knowledge that syphilis is present in one spouse frequently is obtained only after marriage and often results in divorce.
5. Premarital tests will encourage prompt and thorough treatment of syphilis.

Arguments against premarital legislation may be summarized as follows:

1. Serologic tests for syphilis may give nonspecific or falsely positive results. Leprosy, malaria and acute infectious mononucleosis frequently cause positive serologic reactions. More rarely, false positive reactions have been recorded in the presence of tuberculosis, neoplasms, jaundice and fever. As has been stated by one authority:² "To deny a man or woman the license to marry on the evidence of a positive blood reaction alone is risky and seriously open to criticism and objection. In the absence of clinical manifestations or a history at least suggestive of syphilis . . . the serologic test should be indisputable and based not on a single but on at least two positive reactions by two or more methods."

2. Positive reactions alone do not always indicate a danger to marriage. This is especially true if the disease is of long standing or has been thoroughly

treated. The question as to whether a person is or is not infectious to his partner in marriage frequently baffles the specialist and hence is one on which the general practitioner is usually incapable of deciding.

3. Withholding permission to marry will have little effect on the class of society in which the incidence of syphilis is highest and will result in common law marriages and sexual promiscuity.

4. In the incubation period and the primary stage of syphilis, the serologic reaction is often negative. Many men feel they must have a last fling before settling down and may contract syphilis between the time of the blood test and the marriage itself.

5. Emphasis on the legal rather than the medical approach to control is a danger. Premarital examination laws are the forerunners of other laws. The problem of tuberculosis has been well solved without legislation. If marriage is to be under legal control, why not do the job completely and legislate against even greater problems, such as feeble-mindedness?

An effort to assay the value of premarital examination legislation will now be made with respect to

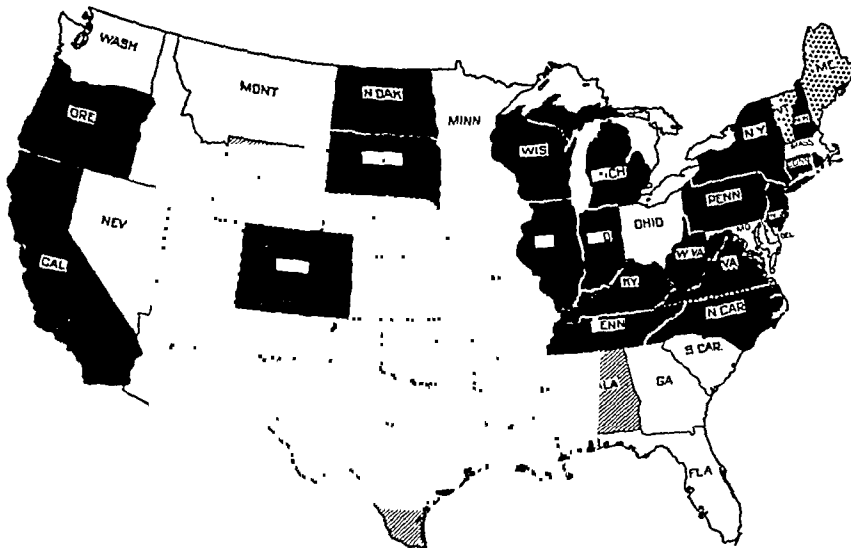

Fig. 1.—Protecting marriage from syphilis. Legislative status of premarital health examinations, 1940. Twenty states (black) require examination by physician of both bride and groom, including blood test for syphilis. Four states (white) require examination by physician of groom only for freedom from venereal diseases. Six states (stippled) prohibit marriage of persons with venereal diseases, some require personal affidavit of freedom from venereal diseases, no examination specified. (From the American Social Hygiene Association, Inc., 1790 Broadway, New York, Oct. 1, 1940.)

the test should be sent to the physician, who forwards it to the health department to be filed and to be used only if further action is necessary to protect the public health. The decision as to issuance of the certificate giving permission for the marriage license should be in the hands of the physician, and he may certify the applicant, even though the test gives positive results, if he does not feel that the disease is infectious. Otherwise treatment must be given and the immediate issuance of the certificate refused. The licensing authority should attach to the license a statement that the applicants have conformed with the law. The person performing the marriage must return the certificate and the marriage license together with his own affidavit. Finally the "ideal law" provides a penal clause and an appropriation to the state health department to cover necessary expenses.

As has been stated, many arguments have been offered, both pro and con, as to the advisability of premarital examination laws. It seems proper to sum-

1. Johnson, Bascom: J. Soc. Hyg. 24: 477 (Nov.) 1938; 25: 285 (June) 1939.

2. Kolmer, J. A.: Laws Requiring Premarital and Pregnancy Tests for Syphilis. Reasons For and Against, J. A. M. A. 112: 2105 (June 10) 1939.

the number of cases in which previously undetected venereal disease is diagnosed, the outcome in cases in which a marriage license is refused and the opinion of the agency administering the law, namely the health department. In May 1940 Mary Edwards published a summary of 631,206 serologic tests done in fourteen states under the new laws. Definitely positive results were obtained in 8,605 instances, or 1.4 per cent. It was estimated that from 70 to 90 per cent of the persons with positive reactions had been previously unaware of their infection. The incidence of positive reactions was about equal for the two sexes, while the ratio of Negroes to white persons varied between 7 to 1 and 20 to 1. Slightly more than half of the total group with positive serologic reactions were granted marriage licenses on the basis of noncommunicability of their disease. Few figures are available as to the behavior of persons refused licenses. A report from New Jersey on 113 applicants states that 71 did not marry, 18 married in other states and the remainder could not be found. Furthermore, more than half were under treatment three months later. It seems to be common experience that the marriage rate in most states rises sharply just before the law goes into effect and falls equally rapidly afterward. This decline, however, has not been found to last more than one or two years, when it rises again to the previous normal rate. It has not been possible for me to seek an expression of opinion as to the advantages and disadvantages of premarital examination laws from the standpoint of the directors of health in the several states employing them. However, I have gathered that their approval is in direct proportion to the closeness with which their state law approximates the so-called ideal law, which has already been cited. Furthermore, it is difficult for me to frame an exact statement of my personal opinion. Every physician will agree that the intent of premarital examination laws, to prevent the spread of syphilis through marriage, is completely appropriate and necessary. The difference of opinion comes as to the manner by which the end may be achieved. Must it be by prohibitive legislation or can it be best accomplished by the medical profession itself with the aid of enlightened public opinion? It seems proper to end this portion of the discussion by quoting briefly from two eminent specialists in venereal disease. J. E. Moore,³ of Baltimore, stated that

emphasis on the legal rather than on the medical approach to the control of syphilis is likely . . . to do . . . more harm than good. Reform by legislative fiat is a procedure which the American people have more than once adopted as a panacea, only quickly to tire, not only of the law itself but of the end at which it was aimed. . . . Perhaps this type of legislation is desirable in the Utopian state, . . . but so far it has not been the American way.

Secondly, Nelson,⁴ of Boston, has summarized his opinion as follows:

Premarital examination, not only for syphilis but for all conditions which make marriage unwise and unsafe, will amount to something and will be conducted on an honest basis when candidates for marriage go to their doctors because they really want to be examined, tell the truth, submit to thorough physical examinations, and accept the physician's opinion as the best opinion that he can give, not as a guaranty. In the meantime,

it is unjust to permit the public to think that it is getting something which cannot possibly be delivered and to put the medical profession in the position of having to swear to the truthfulness of the applicant and the accuracy of the laboratory, and of having to stretch an opinion until it becomes a certificate.

Antepartum examination legislation has created much less argument among physicians and health officers. The laws refer only to syphilis and are practically identical in the various states possessing them. The American Social Hygiene Association has suggested an "ideal law" for antepartum examination also.¹ It is brief and states that a serologic test for syphilis must be made at the time of the pregnant woman's first visit to her physician. The test must be a standard one done in an approved laboratory. On request, the examination will be made without charge by the local health department. The birth certificate of the child should state whether the test has been made; if it has, the date, and if it has not, the reasons why, should appear. The result of the test should not appear on the certificate. Arguments in favor of such a law are:

1. Blood tests during pregnancy represent an excellent method of case finding. Provided a sensitive method is used, it may be said that a definitely positive reaction, verified on repetition, is indicative of syphilis regardless of the history or physical status.

2. The detection of syphilis and its prompt treatment during pregnancy will reduce to a minimum the danger of the offspring being born with congenital stigmas. As a corollary, this often results in more treatment for the woman, since many asymptomatic persons lapse in their treatments between pregnancies but are willing to submit to them while pregnant in order to protect the unborn child.

3. A positive serologic reaction during pregnancy places the physician on the alert and increases the likelihood of repeated examination after birth of the child who otherwise might be neglected in this regard.

4. The detection of syphilis in the pregnant woman will lead to its detection and treatment in other members of the family.

Arguments against antepartum serologic tests are merely the danger of false positive reactions and the fact that the woman who suspects that she has syphilis may go without care or be delivered by a midwife.

Few figures are available as to the practical results of antepartum tests. A report from New Jersey stated that in 1.38 per cent of 19,752 serologic examinations done on pregnant women the results were positive. At the Johns Hopkins Hospital positive reactions were obtained in about 2 per cent of white clinic patients as contrasted with 20 per cent of Negroes. It should be stated that at this hospital the tests were routine and were not compulsory. It seems clear that an attempt to diagnose syphilis is made much less frequently in rural than in urban communities and for mothers delivered at home as contrasted with those delivered in hospitals. Among a group of New Jersey mothers, 56 per cent had been examined and tested for syphilis (according to law) before the seventh month of pregnancy, while a comparative figure of 40 per cent was obtained in New York.

It would seem that much less argument can be brought to bear against antepartum than against premarital examination legislation. Moore, in a personal communication to me, expressed the belief that laws providing for antepartum examination are unnecessary, on the ground that serologic tests during pregnancy are routine in hospitals and in the practice of intelligent

3. Moore, J. E.: *Am. J. Syph., Gonorr. & Ven. Dis.* 23: 386 (May) 1939.

4. Nelson, N. A.: *Am. J. Syph., Gonorr. & Ven. Dis.* 23: 288 (May) 1939.

physicians. Accordingly the law would affect only the few women who are cared for by midwives and ignorant physicians. I cannot agree. In many states whose population is predominantly rural the great majority of women are delivered in their homes. For a large proportion of women so delivered serologic tests for syphilis are the exception rather than the rule. I can see no real argument against antepartum examination legislation except that of expense and wish to go on record as recommending its further adoption.

Until recently syphilis was the largest single cause of premature labor, stillbirth and fetal death. Twenty years ago at the Johns Hopkins Hospital 34.4 per cent of all stillbirths and neonatal deaths were due to this cause, and this figure did not include the large number of infants born alive with congenital syphilis and surviving the neonatal period. Even now 10 per cent of all such deaths at this hospital are due to syphilis, although most of these have occurred when the mother has not received antepartum care. At present congenital

proved. The chances of syphilis being passed on to the child are greatest if the disease is acquired shortly before, at the time of or soon after conception. If the infection occurs after the sixth month, the child will presumably be normal. Furthermore, the probability of transmission in utero diminishes as the number of years between infection and pregnancy increases. These last two statements do not mean that under the conditions stated treatment may be omitted with complete safety to the child.

Until recently it was generally believed that intensive antisyphilitic treatment was no more dangerous to the pregnant woman than to the nonpregnant woman. Minor reactions were disregarded, although a sharp watch was kept for possible hepatic or renal injury. A short time ago this theory was challenged and it was stated that reactions in general, and acute yellow atrophy of the liver in particular, occurred much more frequently after treatment during pregnancy than at any other time. It is probable that further study (preferably statistical) must be done before this question may be regarded as settled. It is, however, the opinion of the syphilis clinic at the Johns Hopkins Hospital that pregnancy itself bears no relation to the incidence and severity of therapeutic reactions.

The treatment of syphilis during pregnancy is primarily concerned with the unborn child, to prevent its becoming syphilitic if possible, and otherwise to treat an already existing infection. A brief outline of the routine proposed by Moore and placed in operation at the Johns Hopkins Hospital follows:

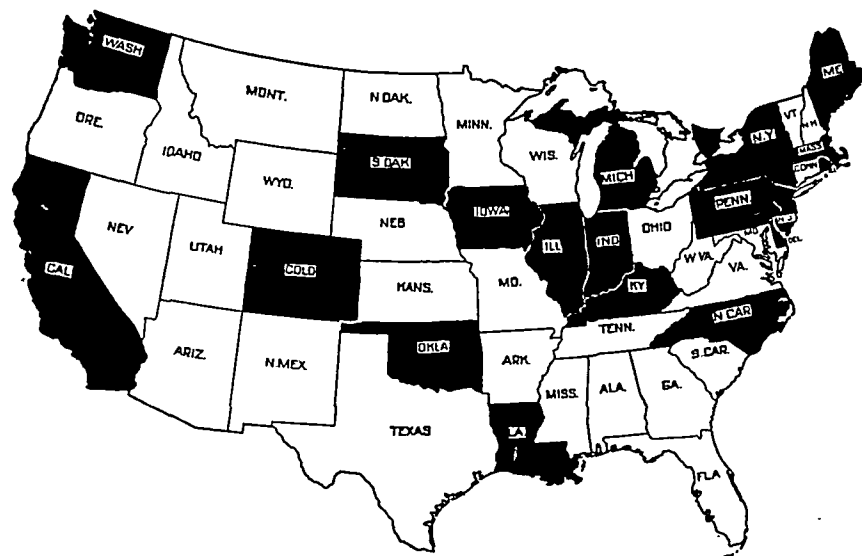

Fig. 2.—Protecting babies from syphilis: Status of legislation requiring physicians to examine pregnant women, 1940. Nineteen states now have such laws. (From the American Social Hygiene Association, Oct. 1, 1940.)

syphilis must be considered as almost entirely preventable, provided routine serologic tests are obtained on all pregnant women and vigorous and adequate treatment is given all those with positive reactions.

Syphilis in pregnant women is usually latent, and only a small minority have a suggestive history or definite clinical signs. Diagnosis, then, must generally depend on serologic study, and a strongly positive reaction verified by repetition must be considered diagnostic. Despite opinion to the contrary, it seems definite that pregnancy does not cause false positive reactions but occasionally results in a false negative reaction. In the Johns Hopkins Hospital series there were 107 patients with false negative reactions, of whom 51 had received varying amounts of therapy and 56 previously had been untreated. It is generally felt that with a negative serologic reaction but with a history suggestive of syphilis, particularly if this includes one or more deliveries of premature or stillborn infants, treatment "on suspicion" is justified. If the husband has syphilis but the reaction of the wife's blood is negative, particularly if the pregnancy ensues soon after marriage, the blood test should be repeated at frequent intervals but no treatment given unless syphilis of the mother becomes

1. If the patient begins treatment before the fifth month, eight intravenous injections of arsphenamine (0.3 Gm.) or neoarsphenamine (0.6 to 0.75 Gm.) are given at weekly intervals, followed by four to six intramuscular injections of a bismuth compound (0.2 Gm.). This routine is repeated to the end of pregnancy.

2. If treatment is begun after the sixth month, the same schedule is used for arsphenamine, but six to eight injections of a bismuth compound are to be given on the same days on which the arsenical is administered.

3. If treatment is started after the eighth month, the foregoing schedule is followed, except that the interval between treatments is shortened to four or five days.

Treatment should never be relaxed, even though it has been started early in pregnancy. Furthermore, the routine should be arranged so that an arsenical is employed for the last three to four weeks prior to the estimated date of confinement. Obviously, therapy should be continued in the usual manner after the pregnancy is over. Finally, it is of the utmost importance that the child be examined carefully and watched closely. The examination should include a serologic test for syphilis on the cord blood, microscopic examination of the placenta, roentgenograms of the long bones, dark field examination of the vessels of the umbilical cord and pediatric clinical and serologic follow-up studies.

The results to be obtained from such a system of treatment are best illustrated by the accompanying table,

taken from a publication by McKelvey and Turner.⁵ Obviously even a small amount of treatment increases the probability of a normal infant's being born. It seems evident that if thirteen to fourteen injections totaling about 4 Gm. of arsphenamine can be administered prior to delivery the danger of congenital syphilis may be eliminated. It is interesting to note from the study of McKelvey and Turner that of 167 babies born with congenital syphilis the mothers of 100 had received no antepartum therapy. Only 16 mothers had received 2 Gm. or more of arsphenamine or its equivalent, and most of these had been treated irregularly or had had a lapse of treatment during the last few weeks of pregnancy. Favorable results to the baby are enhanced if treatment of the mother has been instituted before pregnancy. However, even a large amount of such treatment does not render safe its omission during the gestational period, especially in the case of the primigravida. Combined treatment, including the administration of a heavy metal, gives better results than the use of arsenicals alone. Generally, if the treatment before pregnancy has not been adequate, if the serologic reaction remains positive or if there is clinical evidence

*Outcome of Pregnancy with Varying Amounts of Antisyphilitic Treatment: No Treatment Prior to Pregnancy

of infection, treatment during pregnancy is imperative. Completely adequate treatment, with repeatedly negative serologic reactions, probably protects the child completely even though therapy during pregnancy is not administered.

SUMMARY

The routine employment of serologic tests for syphilis by most hospitals and many physicians, together with the intensive treatment of all patients with positive reactions, has greatly diminished the incidence of antepartum transmission of the disease. Congenital syphilis will practically if not entirely disappear as soon as all pregnant women consult their physicians at a relatively early stage and the value of routine blood tests and treatment becomes universally understood.

ABSTRACT OF DISCUSSION

DR. CARL P. HUBER, Indianapolis: Dr. Peckham's paper presents an admirable summary of present opinion concerning premarital and antepartum serologic tests. In most states, legislation of this type has been so recently enacted that its effect is difficult of evaluation. In Indiana, premarital serologic tests have been required by law since March 1, 1940. During the first year, 66,326 tests were performed, with 1,125 positive reactions, an incidence of 1.69 per cent. The Indiana law corresponds to the "ideal law" suggested by the American Social Hygiene Association and, as in many other states, was adopted in great measure at the demand of the public. There has been

5. McKelvey, J. L., and Turner, T. B.: Syphilis and Pregnancy. *J. A. M. A.* 102: 503 (Feb. 17) 1934.

no great difficulty in its administration. Sufficient time has not yet elapsed to make it possible to evaluate the effect of these tests. It seems pertinent, however, to point out additional values which they may have other than in direct case finding. Such laws are of potential educational value in venereal disease control. A law requiring, as these do, that the partners in a contemplated marriage consult a physician for examination also offers an opportunity for a phase of preventive medicine that is too frequently neglected by both the public and the medical profession. It is an ideal chance to perform a complete premarital examination and to give appropriate advice concerning the medical and sex hygiene problems of marriage and future pregnancy. It is one of the primary steps in any complete program of maternal welfare. Such an opportunity routinely followed up will increase many times the value of an already justifiable law. From March 1, 1940 to Feb. 28, 1941 a total of 31,691 serologic tests were reported on antepartum patients in Indiana by the state board of health and by the approved laboratories throughout the state. This represents slightly more than one half of the number of births which occurred during the same period. There were 520 positive tests, an incidence of 1.64 per cent, almost identical with the incidence in the premarital group. The Indiana law does not require that separate reports be filed on this group of patients, so that in many additional instances blood specimens were not listed as from antepartum patients. The state has looked on the antepartum law as primarily educational in nature. There is no penalty for not complying with it. Its value depends not only on the administration of adequate treatment in positive cases but also on the stage of pregnancy at which the blood is obtained for testing. From that point of view continued education concerning the value of early antepartum care is essential. The effectiveness of the law requiring an antepartum blood serologic test depends, then, on the caliber of antepartum care in any community. The value of this type of law would be increased if an effective means was established to insure adequate follow-up care and treatment for all infants born of mothers with a positive serologic test.

DR. HERMAN BEERMAN, Philadelphia: In a recent evaluation of premarital legislation, Sheppe found 1.3 per cent positive reactions among 677,832 examinations in thirteen states. A large percentage of such patients have latent syphilis, the diagnosis of which depends chiefly on the blood serologic reactions. These reactions are not infallible, especially in the woman. By the application of such a scheme of study for the doubtful case as proposed by Moore and his associates, one can largely eliminate much of the uncertainty in serologic diagnosis. This scheme, briefly, consists in careful physical examination for syphilis and other infections capable of producing a biologic false positive serologic test; a search for malarial parasites; examination of blood smears, and blood tests for infectious mononucleosis; determination of the sedimentation rate; repeated blood serologic tests by different techniques in different laboratories and, if possible, by a quantitative procedure and by special antigens both specific and nonspecific; the performance of the as yet unverified "Kahn verification test"; serologic follow-up; family study, and a cerebrospinal fluid examination. Of course, a cerebrospinal fluid examination should be avoided in a pregnant woman. The provocative procedure is usually worthless, and treatment should be withheld until a definite diagnosis is established. There seems, as Dr. Peckham points out, to be little dispute as to the advisability of antepartum blood testing legislation. I wish not only to support his recommendation of it but to ask for at least two blood tests in pregnancy: one at the time of registration, to detect syphilis acquired anteconceptionally, and one later in pregnancy, about the seventh or eighth month, to uncover syphilis acquired by the pregnant woman during pregnancy. A young white primipara at the time of registration had a negative blood serologic reaction. About three months after registration she had an eruption, which was diagnosed by a dermatologist as a nonsyphilitic condition. No blood tests were made. The eruption persisted, and after delivery at another institution it

was found that the offspring and the mother both had positive blood serologic reactions. On examination, the mother and the father both were discovered to have early infectious syphilis. I agree with the schedule for antepartum antisyphilitic therapy which Dr. Peckham proposes. If syphilis is discovered in the pregnant woman, the possibility of the child's becoming infected depends on several factors. Among these are the age of the infection in the mother, whether she is seropositive or seronegative, the amount and kind of therapy, and the time in pregnancy it is administered. Recent infections and seropositivity are generally less favorable. The more arsenical administered, and the earlier in pregnancy the treatment is begun, the more favorable the outcome with regard to the child. According to the best authority, it is recommended that every pregnant syphilitic woman be treated regardless of her disease and her serologic status, during every pregnancy. In regard to treatment reactions routine blood pressure and urine examination and common sense go a long way in making for safety in the treatment of the pregnant syphilitic woman. Our first year's experience in the Family Syphilis Clinic of the Pennsylvania Hospital, Philadelphia, organized to facilitate early and adequate treatment for pregnant syphilitic women, in which the obstetrician from the Lying-in Hospital and the syphilologist work hand in glove, illustrates the value of adequate antepartum antisyphilitic therapy in the prevention of congenital syphilis. These good results on a relatively small experience can be multiplied by close obstetric and syphilologic cooperation.

DR. CHARLES H. PECKHAM JR., Cooperstown, N. Y.: I should like to state that, whereas twenty years ago it was almost universally agreed that syphilis was the chief cause of premature delivery and stillbirth as well as one of the most common causes of fetal and neonatal mortality, there is a tendency at the present time to feel that the problem has been solved. Recently I have had the opportunity of looking up 1,000 consecutive fetal deaths that occurred in the obstetric service at the Johns Hopkins Hospital over a period of the last ten years. Even at this recent date 10 per cent of the total 1,000 deaths were due to syphilis.

CHEMOTHERAPY IN INFECTIONS OF THE BONES AND SOFT TISSUES

REX L. DIVELEY, M.D.

AND

PAUL R. HARRINGTON, M.D.

KANSAS CITY, MO.

In January 1941, at the ninth annual meeting of the American Academy of Orthopaedic Surgeons in New Orleans, a report was made describing the results obtained in the treatment of infections of bone by the systemic administration and the local implantation of sulfathiazole. Since the general principles on which this method was based were thoroughly covered in this preliminary report, this discussion is limited to the presentation of additional data on the use of sulfathiazole in the treatment of infections in bones and soft tissues, which data have accumulated since that time.

The plan of treatment for osteomyelitis advised in the preliminary report was as follows: first, systemic administration of sulfathiazole in sufficient dosage to secure a blood concentration of approximately 5 mg. per hundred cubic centimeters several days before operation, thorough débridement of the infected area, implantation of sulfathiazole crystals into the wound, primary closure and application of a plaster dressing for fixation. In the management of compound fractures, the same procedure was followed with one modifi-

cation: in fresh compound fractures, since débridement cannot be delayed in order to secure a satisfactory blood concentration of the drug, sodium sulfathiazole was administered intravenously. In this way a fairly high blood concentration could be built up very rapidly. In old compound fractures, the preliminary treatment carried out was the same as that used in osteomyelitis.

In compound fractures, the local treatment was carried out as follows:

1. A tourniquet is applied to the extremity to be operated on and remains in place until the plaster dressing is applied for immobilization following the operative procedure.
2. The superficial tissues are thoroughly cleansed and washed with ether, and all foreign material is removed.
3. The cutaneous edges of the compound wound are excised for a distance of at least $\frac{1}{4}$ inch, all devitalized skin being removed.
4. The soft tissues are then thoroughly debrided, all traumatized and devitalized tissue being removed. This is the most important step of the entire procedure.
5. All detached bone fragments are removed.
6. The bone ends are brought into alinement and held by a bone clamp.
7. Internal fixation is applied, a silent metal such as vitallium, being used.
8. The wound is cleansed with warm saline solution and thoroughly dried.
9. Sulfathiazole powder is now introduced into the wound. This is most effectively done by using a nasal insufflator, since in this way the powder is deposited in a thin layer over the bone and into the most minute crevices of the wound. Generally, from 1 to 3 Gm. of powdered sulfathiazole is sufficient.
10. The deep soft parts are sutured with interrupted catgut in such a manner as to bring them into as close contact as possible with the denuded area of bone. Following the suturing of the deep layer, additional sulfathiazole is introduced into the wound, and the superficial structures are closed with interrupted sutures. The skin is closed with cotton thread. A firm dressing is applied over the wound, and if there are any areas of denuded skin a thin layer of petrolatum gauze may be applied over these wounds. Finally, a plaster dressing is applied adequately to immobilize the extremity.

It should be clearly understood that the plan of local treatment described refers only to injuries in which the wound and the soft parts are of such character as to permit closure without tension and on patients who are to remain under the supervision of the surgeon. It could not properly be applied in war casualties in an action or movement, nor when there is extensive loss of soft parts. In this type of case, the wound should be left open and tamponed after the local introduction of sulfathiazole.

The first time that this procedure was used was Aug. 1, 1940, and since that time 56 patients have been treated by this method. This series is divided into subacute and chronic osteomyelitis (38 cases), compound fractures (16 cases) and miscellaneous infected wounds (2 cases). The latter group represents (1) an infected sinus in the thigh of about eight years' duration and (2) an infected ulcer of the foot. In both of these cases healing was by primary intention.

In the 56 cases reported, the age range was from 2 to 70 years. The average age was 24.6 years. The average total dose of sulfathiazole by mouth was 57.4 Gm. and the average daily dose was 5.3 Gm. The average blood concentration was 4.3 mg. per hundred cubic centimeters of blood. The average amount of the drug used locally was 1.9 Gm. The average healing time was twenty-one and six-tenths days.

The number of cases of chronic osteomyelitis was 38. Two unhealed cases were listed in the preliminary report—one an osteomyelitis of the femur of *Escherichia coli* origin, and the other an osteomyelitis of the mandible. The first of these cases, by the alternate use of the Carrel-Dakin method and sulfathiazole, healed in fifteen weeks and has remained healed. The patient with osteomyelitis of the jaw was reoperated on and a small piece of sequestrum was found and removed. Since then the wound has remained healed.

We wish at this time to report an additional case of osteomyelitis which failed to heal by primary intention. This case was one of osteomyelitis of the femur of thirty years' duration during which time numerous operations had been performed to clean up the condition. At the time it was operated on more than half of the circumference of the femur was removed for approximately two thirds of its length. Following the operation the Carrel-Dakin treatment was employed for two weeks, at the end of which time the wound was closed with introduction of sulfathiazole powder. The wound broke down in about two weeks and the Carrel-Dakin treatment was again administered for three weeks. At the end of this period, the Orr method of treatment was used. The cavity was, however, thoroughly insufflated with sulfathiazole powder before the petrolatum gauze was introduced and a cast applied. The Orr method was used at this time because economic conditions made it desirable for the patient to leave the hospital and return home. In this case healing is rapid and the result should eventually be successful but with a greatly prolonged healing time compared to the others.

The cases of compound fractures numbered 16. The age range of the patients was from 10 to 66 years, the average age being 36.9 years. The average total dose of sulfathiazole by mouth was 566 Gm. The mean average daily dose was 66 Gm. The average blood concentration was 4.7 mg per hundred cubic centimeters of blood. The average amount of the drug used locally was approximately 2.6 Gm.

Of interest is the comparison of blood concentration with the use of the sodium sulfathiazole given intravenously to that of the sulfathiazole given by mouth. Six-hundredths Gm of sodium sulfathiazole per kilogram of body weight was given intravenously, the average dose being 4.1 Gm. The average blood concentration after the lapse of five minutes was 47.5 mg per hundred cubic centimeters, one hour 12.15 mg, two hours 10.75 mg, three hours 7 mg and four hours 5.25 mg.

The mean average daily dose of sulfathiazole given by mouth was 66 Gm. The average blood concentration after the lapse of one hour was 4.2 mg per hundred cubic centimeters, two hours 4.1 mg, three hours 5 mg, four hours 5.9 mg and eight hours 4.7 mg.

The temperature, pulse, respiration and combining power of carbon dioxide were not materially affected by the one dose of sodium sulfathiazole that was given. Crystals of the drug were recovered in the urine at the end of one hour, but otherwise the urine was normal throughout the concentration period.

Eleven cases were of acute compound fractures and operation was performed within twenty-four hours. In 5 cases the compound fractures were old with persistent infection. The mean average healing time for this series was twenty-four and eight-tenths days. (Two cases of this series are of too recent occurrence to be reported, but both seem destined to satisfactory healing. Three other cases are to be reported later.)

CONCLUSIONS

In a series of 56 cases of infected bone and soft tissue the treatment employed was the administration of sulfathiazole by mouth or sodium sulfathiazole intravenously, thorough débridement of the focus and the introduction of sulfathiazole powder into the wound. In 53 cases healing was by primary intention with an average healing period of twenty-one and six-tenths days. Two cases should be termed successful but with a greatly prolonged healing time as compared to the others. One case we consider a failure as regards this method, but the case is still under treatment.

1400 Professional Building

ABSTRACT OF DISCUSSION

DR FRANCIS M. MCKEEVER, Los Angeles. I am not qualified by large experience with chemotherapy in fractures to discuss this paper. In my series of compound fractures there were 77 patients. The small puncture compound fractures were not a great problem. Most of them healed primarily. It had been my impression that a good débridement gave a high percentage of good results. However, in the large lacerated wounds the percentage of primary healing was not high. It was a disappointment. A small group was treated by local chemotherapy and by closing the wound, and, although this group is very small, it is suggested that the method is effective and that the sulfanilamide drug should be used locally as well as systemically. As far as the method of treating old osteomyelitis by dissecting out the sinuses and filling the wound with sulfathiazole is concerned, I have tried it in only 5 cases. I must say that despite my skepticism it has worked in 5 instances consistently. I should like to ask the authors what attitude they take toward the puncture wound fracture. Do they feel that it is worth while to open this wound widely so that the chemical can be disseminated throughout the injured tissue? I should also like to ask whether in their longer follow-up of the cases of chronic osteomyelitis some of the wounds which were healed early have later on formed abscesses and drained.

DR ROBERT W. JOHNSON, JR., Baltimore. It would seem that we have a problem here of two types of injury, severe soft part injury with fracture, the severe compound fracture, and the puncture wound fracture. I think we are pretty well convinced that the puncture wound fracture had dynamite in it, potentially but not surely, whereas the severe compound fracture is a tremendous problem for us all the time. I was struck by an omission on my part to use the intravenous drug in these cases. I think that is a definite protection which should be offered to the patient of which the authors have made good use. The one point on which I find myself in disagreement with Drs. Diveley and Harrington is that in a compound fracture seen early the most dangerous organisms which are potential invaders are the gas bacillus group and the streptococci. Now sulfanilamide is very much more potent with those than sulfathiazole. I like to use sulfathiazole only when there is pretty good evidence that the staphylococci are the infecting organisms. I believe that it would be wiser to use sulfanilamide in the first thirty-six to forty-eight hours and then switch to staphylococcus specific and use the sulfathiazole group later. Certainly, in the case which they showed us in the movie which was ninety-six hours old the drug of choice would be sulfathiazole, because it was evident that there was not a gas infection and probably not a streptococcal infection in a wound that looked like that. The main point, however, is that here we have a series of drugs which have tremendous potentiality to help us. We must learn how to use them. We must learn how to couple them with surgical procedures. We are faced with the problem of the individual compound fracture in which the degree of bone damage, circulation, soft tissues, the duration of time since the accident occurred and the character of the ground introduce, one might say, a hundred different variables, and the point that I should like to end on is that, while we have powerful aids now which we have not had in the past, there is still no substitute for surgical judgment.

DR. REX L. DIVELEY, Kansas City, Mo.: There are many points that we hope to prove in the future. As Dr. Johnson has said, possibly sulfanilamide can be used more effectively as far as the prophylaxis against the streptococcus and gas bacillus are concerned. Dr. McKeever has mentioned puncture wounds. Small puncture wounds without a great deal of traumatism to the soft tissues I do not believe need to be disturbed. We, of course, sterilize the nozzle of the insufflator, and this can be introduced into the wound and powder can be thoroughly instilled into the wound without an extensive débridement. He mentioned abscesses which might appear later. Unquestionably we are going to have some kickbacks from this procedure. While our results are seemingly excellent at the moment in our particular series, the method is less than a year old. We shall know a lot more at the end of a few more years.

HEPARIN IN SUBACUTE BACTERIAL ENDOCARDITIS

REPORT OF CASES AND CRITICAL REVIEW OF LITERATURE

JAY McLEAN, M.D.

B. B. M. MEYER, M.D.

AND

J. M. GRIFFITH, M.D.

COLUMBUS, OHIO

CASE 1.—History.—Ann Arnholt, aged 19, an Ohio State University student, was admitted to the White Cross Hospital, Columbus, March 5, 1940. In October 1939 the present illness began with acute inflammation of the upper respiratory tract, fever, anemia, cessation of the menses, swollen joints and a mitral systolic murmur at the apex. The clinical diagnosis was acute vegetative endocarditis. Blood cultures were negative until November 16, at which time a long chain nonhemolytic streptococcus was obtained. Administration of sulfapyridine was discontinued owing to severe vomiting. In December and again in February 1940 she had a cerebral accident which on the first occasion partially paralyzed her right arm and on the second occasion the left arm and left side of the face. In March vision was blurred, acuity of hearing failed and headaches and urinary frequency developed. Repeated cultures through March 12 were reported as a short chain streptococcus. During the period from the onset, October 1939, to admission, March 5, 1940, she had lost 65 pounds (29.5 Kg.). On admission she was greatly dehydrated, weak, partially paralyzed in both arms and one leg, suffered headaches and was very nervous and fretful. The patient was brought to us because her parents had read of the treatment of bacterial endocarditis with heparin. The dangers of the treatment were carefully explained to the parents.

Clinical Course in Hospital.—The duration from admission to death was twenty-seven hospital days—March 5 to March 31 inclusive. During the first seven days measures were carried out to combat her general poor condition. Heparin was administered during the next fifteen days and no heparin was given the last five days. Sulfapyridine was given daily from the second to the twenty-fifth day in amounts shown on the chart (fig. 1); also charted are the fluid intake and urinary output. Sulfapyridine caused nausea and vomiting throughout. After the priming dose, heparin was administered through a needle inserted in the saphena-magna vein at the ankle; however, heparin was discontinued for three days from March 19 to March 22 because the needle assumed a position which impeded intake of the heparin and saline solution and to give the patient a rest from continuous drip therapy. The needle was then inserted in the vein of the other ankle.

The coagulation time was determined daily (method of Lee and White) at the same hour by the same technician. The normal coagulation time was four and five minutes on admission. Under heparin treatment the tests were reported as but six and one-half to seven and one-half minutes.

Mentally she improved considerably after the heparin administration was begun, and she maintained this apparent improvement until after the cessation of heparin treatment. In spite of the nausea caused by the sulfonamide drug, she ate and slept better, and the nurses who were with her twenty-four hours a day reported that she used her partially paralyzed limbs better than before. The heparin was stopped two or three days earlier than had been anticipated, owing to the sharp decrease in the urinary output, which occurred on the twenty-fourth hospital day (fig. 1). This was coincident with moderate generalized edema.

On the twenty-sixth hospital day—three full days after the cessation of heparin and the day before death—the patient seemed considerably improved, moved her left arm and leg and talked about going home. The morning of the twenty-seventh day severe edema of the face, hands and ankles developed. Her nails were cyanotic, respirations were shallow and labored, the pulse was weaker and the heart had a gallop rhythm. Oxygen was administered, but the patient lapsed into coma and died during the evening of the twenty-seventh day.

Dr. R. S. Fidler of the White Cross Hospital made the postmortem examination, which we witnessed. It revealed no thrombus either proximal or distal to the insertion of the needles used for heparin administration. The spleen was twice the normal size, contained numerous infarcts, old and recent, the largest of which were 2 cm. in diameter. The stomach and first part of the duodenum showed mucosal hemorrhages. Numerous old kidney infarcts were present, the largest 1 cm. in diameter, with no recent kidney infarcts. The abdominal and thoracic cavities and pericardium contained a large amount of straw colored fluid. The heart showed destruction of the aortic valve, as shown in figure 2. The arachnoid was found distended with a brownish fluid. There was brownish discoloration over the left parieto-occipital area, and an old hemorrhagic area at the middle portion of the right cerebral artery. The ventricles showed no pathologic changes, and no recently infarcted areas or emboli could be found. Microscopic sections showed the aortic cusp and the surface of the valve covered with a fibrinous thrombus beneath which there was some proliferation of endothelial cells. Within this superficial thrombus were colonies of bacteria. Beneath the endothelial layer was a productive fibrosis with a moderate infiltration of pus cells and lymphocytes. The blood vessels of the duodenum were engorged with blood but were not thrombotic. The final diagnosis was:

1. Acute and subacute vegetative bacterial endocarditis of the aortic valve invading the mitral valve.
2. Acute and subacute myocarditis.
3. Embolic infarcts of the middle cerebral artery, kidneys and spleen.
4. Subarachnoid edema with old hemorrhage.
5. Superficial mucosal hemorrhagic degeneration of the gastrointestinal tract.
6. Generalized edema of the subcutaneous tissues, ascites and pleural and pericardial effusion.
7. Infantile uterus with fibrosis and follicular cysts of the ovaries.

CASE 2.—History.—L. T., a woman aged 37, had onset of symptoms three months before her hospital admission, Nov. 2, 1939. Repeated blood cultures were positive for *Streptococcus viridans*. She was treated with sulfapyridine, which rendered the blood negative for a while.

Course in Hospital.—During her first twelve hospital days the temperature curve showed daily rises to 102 and 103 F., and she complained of occasional attacks of pain in her left shoulder. Two days later she received 500 cc. of whole citrated blood. On the nineteenth hospital day a continuous intravenous drip of 30,000 units of heparin in 1,500 cc. of physiologic solution of sodium chloride was started with the chemotherapy. During this procedure her temperature curve demonstrated a daily fluctuation (99 to 100 F.). In a few days she became

1. Dr. S. A. Hatfield gave the authors permission to report this case, which was under his care at the Ohio State University Hospital.

severely nauseated and demonstrated some edema of the ankles and of the right hand and arm. By the seventh day of heparin treatment her clotting time had increased to one hour and fifteen minutes. She complained of severe headaches and vomiting. Heparin therapy was discontinued and her temperature rose to 103 F. and she began voiding and defecating involuntarily. Her extremities became cold and she would not respond to any stimuli. Blood pressure rose to 178 systolic and 100 diastolic and caffeine and sodium benzoate were given; also daily clysis of 1,000 cc. of 5 per cent dextrose in physiologic solution of sodium chloride was administered. On the sixth day of coma she regained partial ability to speak, but a slight twitching of the left side of her face and of her left arm was noted. Speech gradually improved. During the course of the next month her temperature ranged between 100 and 103 F. She complained frequently of severe pain in her head, abdomen, shoulder, legs and arms. Culture of her blood became positive and her spleen palpable. On the eighty-first hospital day she complained of the sudden onset of a red and painful area over the dorsum of her left foot. Twenty days later she had severe headache

and Katz,³ first proposed the physiologically attractive theory of the use of heparin for this condition, states that he now believes it to be of no value. And Fletcher, after an experience with one case⁴ and a second case a year later,⁵ states that the use of heparin should be discontinued; finally Blumer⁶ writes that the method as used should be abandoned. However, improvement in cases reported by Kelson and White,⁷ as well as several cases reported by various authors which apparently showed improvement clinically while under treatment, has given some authors hope that further trial might be justifiable, and this view has been editorially supported wholly or in part.⁸

If Friedman, Hamburger and Katz's original theory is to be experimentally tested, we doubt whether the plan of heparin treatment used by them and followed by subsequent workers constitutes an adequate test of the theory. We doubt whether the entire plan of

Fig. 1 (case 1).—Clinical observations from March 5 to March 31.

and a painful abdomen and again she voided involuntarily. On the following day spasmodic twitching of her left arm and an occasional attack of a convulsive seizure occurred. The temperature rose to 105 F. and her pulse became rapid and weak. Respirations were shallow and irregular. She exhibited extreme peripheral cyanosis, dyspnea and coldness. She died on her one hundred and first hospital day with the diagnosis of sub-acute bacterial endocarditis.

Dr. Emmerich von Haam made the autopsy report. This patient also had multiple infarcts of the spleen and kidneys and likewise involution of the ovaries and uterus, as well as old cerebral hemorrhage. In addition to the pathologic picture of valve damage, she showed recent meningeal hemorrhage as the cause of death.

CRITICAL REVIEW

We see no value in a computation of the percentage of improvements in this series. Certain cases would have to be deleted for various obvious reasons. The incidence of subarachnoid and cerebral hemorrhage is alarming. There is no reason to believe that other cases known to have been under treatment by this method, but which have not been reported in the literature, fared better. Friedman,² who with Hamburger

subjecting the patient to the effects of heparin, sulapyridine and a large quantity of fluid simultaneously—all within two weeks—is judicious.

We recognize the amount of heparin given and the duration of administration as the same which are used for the prevention of postoperative thrombosis. Crafoord⁹ has shown that in the same patients a greater heparin dosage is needed after operation to produce a given prolonged coagulation time than before operation; and Rojak¹⁰ in a series of 67 operative and non-operative cases has shown that in postoperative conditions additional heparin is required to attain a given

prolongation of the coagulation time. The amount of heparin used in treating postoperative thrombosis is based not only on the necessity of maintaining the blood at a higher incoagulable level but also on the necessity of neutralizing the thromboplastic substance (cephalin) which is freed in the course of an operation. The neutralizing action of cephalin and heparin on each other almost prevented the discovery of this anticoagulant.¹¹ This free cephalin does not exist as such in bacterial endocarditis, and therefore an amount of heparin to neutralize it is not required.

Further, the overdosage of heparin may be just the additional amount required to cause untoward complications such as those reported by Kleiber¹² and Witts,¹³ namely more or less renal hemorrhage. This may occur even in massive quantity, as was reported recently.¹⁴

While an extremely prolonged coagulation time of one to five hours, which has been produced by this amount of heparin, may not in itself be dangerous, apparently the effects of the extreme fluidity of the blood produced by this dosage has been overlooked.

Fig. 2 (case 1).—Destruction of aortic valve. Vegetations may easily become emboli.

In a patient who may have vegetations suspended by a fibrin thread in a heart whipped to feverish activity, this excessive fluidity may cause emboli by the mechanical factors present and produced. Even the earliest (1916) preparations of cuorin and heparphosphatid¹⁵ produced such fluidity. Since emboli developed in so many cases while under treatment or shortly thereafter, the amount of heparin used and the fluidity of the blood occasioned by it appear to be the probable precipitating causes. A dosage based in part on body weight should be considered.

The duration—two weeks—has proved adequate to prevent postoperative thrombosis, but we doubt whether the healing required in the vegetations could be accomplished within this period; on the other hand, heparin

given by continuous intravenous drip could not be tolerated longer by these very sick patients.

It is questionable whether the amount of fluid administered as heparin solvent is not immoderate in a patient with a badly damaged heart, and possibly, if not probably, with diminished kidney function due to preexisting infarcts. The amount of fluid used and the concentration of the heparin are essentially the same as those used in prevention of postoperative thrombosis; however, in these cases the heart is presumably normal and the fluid itself has a definite value. Added to this is the fact that continuous intravenous injections by the drip method are extremely difficult to regulate for uniform delivery of either the medium or the solvent.¹⁶ However, an efficient control of such a slow and prolonged procedure was obtained by the use of the rotary pump.¹⁷ Certainly if the intravenous drip method is to be used the fluid intake and the urinary output should be carefully charted.

In Sweden very good results have been obtained by single intravenous injections of heparin every six hours, although Rojak's work would indicate that a more uniform incoagulability of the blood could be maintained by injections every four hours. This would obviate the necessity of administering so much fluid and probably be adequate for the purpose to be accomplished in treating bacterial endocarditis. It would also eliminate much nursing expense. Murphy, Correll and Grill¹⁸ have recently pointed out the dangers of intravenous solutions. The single injection method, however, has the disadvantage of rapid elimination of heparin from the blood stream. If the continuous injection method is to be continued, the pump should be used and the amount of heparin and fluid reduced.

The question of the simultaneous use of heparin and a sulfonamide drug also arises; for the vomiting which is a frequent untoward effect of sulfapyridine may cause a further strain on the heart and thus contribute to the mechanical effects causing emboli. Some work has been done by N. A. David and his associates¹⁹ to reduce the various untoward effects of the drug. Swain's²⁰ recommendations for in vitro tests of the organism's susceptibility to the sulfonamide drug should be carried out if its use is to be continued. However, if Friedman, Hamburger and Katz's original theory is to be tested, we believe that, since the blood is known to possess a high titer of antibodies for the organisms and since the main problem is not the sterilization of the blood stream, heparin should be allowed to act alone in preventing further valve deposits and permitting old ones to heal. This should be tested without complicating the picture by the simultaneous use of sulfapyridine. The fluidity of the blood caused by heparin, even in moderate dosage, may increase the amount of antibodies present in the relatively avascular valves.

Selection of cases in this series does not seem to have taken place. Apparently the cases were accepted as they became available. A summary of 67 cases is

given in the accompanying table.²¹ While it is difficult to determine just what is an old or a recent subacute bacterial endocarditis (the basis of a damaged heart may have originated in childhood), still we believe that a patient such as ours who was almost moribund on admission is not suitable for the treatment unless the plan of treatment in the future is radically altered.

CONCLUSIONS

1. The results secured in this series of 67 cases do not warrant further trial of the treatment by heparin according to the plan used.

2. If heparin treatment is to be continued, we believe that the various factors which must be considered before treatment is given, as well as be controlled during treatment, will require the cooperation and facilities afforded by a group of scientists working in an institute for medical research which could admit an adequate number of selected cases for a suitable duration.

HIGH VOLTAGE ROENTGEN TREATMENT OF ELUSIVE ULCER OF THE BLADDER

A REPORT OF A CLINICAL STUDY OF
TWENTY-FIVE CASES

HERMAN L. KRETSCHMER, M.D.

AND

F. H. SQUIRE, M.D.

CHICAGO

This paper is based on a clinical study of 25 patients given high voltage roentgen therapy in whom the diagnosis of elusive ulcer was made. The various forms of treatment that have been advised and employed, from wide resection of the ulcer-bearing area to fulguration, are legend and it is not necessary to review them at this time. Suffice it to say that when the treatment of elusive ulcer is discussed and all the various forms of treatment are mentioned, the use of roentgen rays is mentioned as casually as are some of the other forms of treatment. So far as we know, a study of a group of similar cases treated with high voltage roentgen therapy has not been reported.

Because of the paucity of reports of the results of treating elusive ulcer with high voltage roentgen rays, and because of the present trend to treat inflammatory conditions elsewhere in the body with roentgen rays, it occurred to us to treat a series of patients to determine whether or not roentgen therapy is of any value in elusive ulcer.

The 25 patients were studied in two separate groups: The first group, consisting of 10 women, were studied

in 1932 and 1933, and the second group, consisting of 12 women and 3 men, were treated in 1938 and 1939.

In order to avoid producing an artificial menopause with its distressing symptoms, the women selected had all reached the menopause. The first group of patients received fulguration and water dilation along with roentgen therapy. The specific factors used were as follows: Four fields, 15 by 15 cm., two anterior and two posterior, were treated daily with 140 kilovolts, 5 milliamperes, 25 cm. target skin distance, 0.25 mm. of copper and 1 mm. of aluminum filter, one area being given 200 roentgens daily, with a total dose of 600 roentgens to each area with each course of treatment. The total dose to the pelvis was 2,400 roentgens. This course was repeated two to four times at six week intervals, depending on the patient's local and systemic reactions.

All the patients had an increase in their bladder symptoms during the course of treatment which persisted for about two weeks. Following this there was some temporary improvement in about 50 per cent of the patients, and 2 patients were definitely improved. The remaining 8 patients had no permanent improvement.

Because of the improvement noted in these 2 cases it was decided to study a second group of cases in which roentgen therapy only was used after other forms of treatment had failed. The specific factors used in this group were as follows: Two fields of 15 cm., one anterior and one posterior. The following physical factors were used: 200 kilovolts, 10 milliamperes, 0.5 mm. of copper, 1 mm. of aluminum filter and 50 cm. target skin distance, delivering 200 roentgens daily to alternate portals; 600 roentgens was given to each area in each course of treatment. The total dose to the pelvis was 1,200 roentgens. Two or three courses of treatments were given to these patients at six week intervals.

During the course of treatment these patients experienced a definite increase in their bladder symptoms which continued for about two weeks after treatment. Again some temporary relief was noted in half of the patients. Follow-up cystoscopies and clinical observations failed to disclose a single case of permanent relief by roentgen therapy.

This group of cases was closely followed by repeated cystoscopies, and while here and there there seemed to be an activation of the process for the time being, in that there appeared to be a little more redness in the ulcer-bearing area at the end of the treatment, whatever local reaction may have occurred soon disappeared and so far as one could tell from cystoscopy there was no change in the character of the ulcer-bearing area. In no case was the patient any worse after the treatment than before.

SUMMARY

Roentgen therapy as we administered it in this group of cases failed to effect a permanent cure in a single case. During the treatment there was an acute exacerbation of the bladder symptoms, which disappeared, followed by some relief of the symptoms. This relief was transitory in all cases. Our experience, therefore, in treating a well selected group of elusive ulcers which were not benefited by previous treatment and in which only roentgen therapy was given verifies the general impression that high voltage roentgen therapy is of little value in the treatment of elusive ulcer.

Clinical Notes, Suggestions and New Instruments

HODGKIN'S DISEASE OF THE HEART AND PERICARDIUM

CURTIS F. GARVIN, M.D., CLEVELAND

Murchison¹ was the first to describe involvement of the heart in Hodgkin's disease. The condition is rare, as indicated by recent reviews of the literature.²

This communication reports a case of Hodgkin's disease in which the appearance of symptoms of myocardial insufficiency led to a clinical diagnosis of cardiac involvement. The administration of high voltage roentgen therapy seemed to cause temporary improvement.

REPORT OF CASE

B. U., a white woman aged 27, entered the Cleveland City Hospital on Dec. 21, 1929. She had had enlarged cervical lymph nodes for one month. A biopsy revealed Hodgkin's disease. During the following years high voltage roentgen therapy was administered periodically to the neck, axillas, groins and trunk for involvement of the lymph nodes in these regions.

In 1935 she was in good enough health to have an operation for appendicitis and three months later one for chronic cholecystitis and cholelithiasis.

In January 1938 she began to be short of breath and to cough. A film of the chest, Jan. 12, 1938, showed enlargement of the mediastinal nodes and considerable infiltration of the upper lobe of the left lung, presumably due to Hodgkin's disease. The transverse diameter of the cardiac shadow was 14 cm. as compared to 11 cm. in previous films.

The patient received roentgen therapy³ to the upper left portion of the chest anteriorly and posteriorly in 100 r fractions daily for twenty days, starting January 19. Films of the chest taken January 31 and February 15 showed progressive diminution in the parenchymal involvement, and the patient felt better. The transverse diameter of the heart remained the same.

Shortness of breath recurred and a film of the chest on August 3 showed the cardiac shadow to be further enlarged, measuring 16.5 cm. in its transverse diameter (in relation to the greatest internal thoracic diameter of 29 cm.). The upper lobe of the left lung showed streaked mottling, presumably due to fibrous healing.

Because the shortness of breath became worse, the patient was admitted to the hospital November 3. She was given high voltage roentgen treatments to the upper anterior and posterior portions of the mediastinum in 200 r doses on ten successive days, starting November 14. She was discharged November 30, her condition being improved. Films showed that the transverse diameter of the cardiac shadow had decreased to 14 cm.

The dyspnea returned, however, and edema of the legs appeared. When admitted to the hospital Jan. 2, 1939, she presented the picture of heart failure. She was orthopneic, the legs were edematous, the liver was enlarged and tender and there was fluid in both pleural spaces. The heart was enlarged and showed a gallop rhythm but no significant murmurs. The blood pressure was 100 systolic and 70 diastolic. On the eleventh hospital day the cardiac mechanism was auricular fibrillation.

An electrocardiogram, January 4, showed tachycardia of unknown origin, low voltage of the QRS and T waves in all leads and an inverted T wave in lead 2. One taken January 11

showed auricular fibrillation, low voltage of the QRS and T waves in all leads and an inverted T wave in lead 2. The serum albumin was 3.5 Gm. per hundred cubic centimeters of blood and the globulin 2.3 Gm. per hundred cubic centimeters. A film of the chest, January 5, showed the mediastinal and cardiac shadows to be unchanged.

Rest in bed, digitalis, aspiration of the pleural effusions and symptomatic treatment brought about moderate improvement. The enlarged cardiac shadow, the myocardial insufficiency, the auricular fibrillation and the abnormal electrocardiogram were now ascribed to involvement of the heart by Hodgkin's disease. The patient was discharged January 30.

A recurrence of the symptoms and signs of myocardial insufficiency caused her readmission to the hospital March 2. The cardiac mechanism at this time was normal. A film of the chest showed infiltration in the right hilus region and the upper half of the right lung. The infiltration in the hilus region made it impossible to measure the width of the cardiac shadow. The patient was given high voltage roentgen therapy to the upper half of the mediastinum anteriorly in 200 r doses on alternate days for four treatments, from April 18 to April 24. She also received digitalis and mercurial diuretics. She was discharged April 29, her condition being improved.

The patient was in the hospital again from June 6 to June 10. Her general condition was slightly improved. The cardiac mechanism was normal. The mottling in the right lung field had diminished. The transverse diameter of the cardiac shadow had further decreased, measuring 13 cm. There was evidence of only slight myocardial insufficiency.

She returned to the hospital on August 7 and stayed until September 3, at this time receiving roentgen therapy for enlarged abdominal lymph nodes. There was no evidence of heart failure.

During the next nine months, although her condition was poor, she was well enough to be cared for in the outpatient clinic, where periodically she received an injection of a mercurial diuretic.

June 10, 1940 she was admitted to the hospital in a moribund condition, emaciated, semistuporous and orthopneic. The cardiac mechanism was normal. The legs were edematous. She died fifteen hours later.

The clinical diagnosis was Hodgkin's disease with involvement of the lungs, mediastinum and heart and chronic myocardial insufficiency.

AUTOPSY

Autopsy was performed by Dr. A. E. Margulis seven hours after death. The body was normally developed and poorly nourished. Except for pallor of the skin and mucous membranes and pitting edema of the extremities, the external examination was negative.

The base of the heart, the aorta, the pulmonary artery and veins and the venae cavae were encased in a dense tumorous mass which filled most of the mediastinum and extended into both lungs. This tissue was dense and cut with definite resistance. The sectioned surface was gray and uneven, with slightly raised opaque areas intermingled with depressed, somewhat translucent areas. The lumens of the great vessels were not occluded or invaded, although they were compressed more or less and it was impossible to trace the venae cavae completely.

The mediastinal mass had extensively invaded the atrial walls, particularly that of the right atrium. Near the opening of the inferior vena cava the tumor tissue extended through the atrial wall and appeared as an irregular polypoid mass in the right atrial cavity. The uninvolved portions of the heart were normal. The pericardial space over the atria was obliterated—otherwise it was normal.

The right lung was more or less completely infiltrated with tissue similar to and continuous with the mediastinal tissue. The left lung was uninvolved except in the hilus region. There was a single subpleural nodule measuring 1 cm. in diameter and located in the upper lobe.

In the retroperitoneal area encasing the aorta and the inferior vena cava there was a large dense ovoid mass of tumor tissue measuring 8 by 8 by 15 cm. and extending from the diaphragm

From the Department of Medicine of Cleveland City Hospital and Western Reserve University School of Medicine.

2. Harrell, G. T.: Hodgkin's Disease with Invasion of Pericardium and Gallbladder: Review of Literature and Report of Case with Autopsy, *Arch. Path.* 28: 58-64 (July) 1939. Ritvo, Max: Hodgkin's Disease: Report of a Case with Unusual Longevity and Invasion of the Heart and Pericardium, *New England J. Med.* 223: 891-895 (Nov. 28) 1940.

3. The factors utilized in the high voltage roentgen therapy were 200 kilovolts, 20 milliamperes and 0.75 mm. of copper plus 2.0 mm. aluminum filtration. The target-skin distance varied between 50, 60 and 70 cm. The size of the ports varied from approximately 50 to 150 square centimeters.

to the second lumbar vertebra. This tissue had destroyed the left adrenal and had invaded the capsule of the liver at one point.

The spleen was moderately enlarged, being the seat of tumor involvement and chronic passive hyperemia. The other viscera showed chronic passive hyperemia. No lymphadenopathy was discovered.

Microscopically the tumor tissue had all the histologic features of Hodgkin's granuloma. Sections from the base of the heart showed extensive involvement and destruction by this tissue of the parietal and visceral pericardium, and to a lesser extent of the myocardium. The uninvolved myocardium was normal.

The spleen and right lung showed considerable Hodgkin's tissue and chronic passive hyperemia.

The diagnosis was Hodgkin's disease with involvement of mediastinum, lungs, great vascular trunks, pericardium, heart, spleen, retroperitoneum, left adrenal and capsule of the liver.

COMMENT

The rarity of involvement of the heart or pericardium in Hodgkin's disease has been mentioned. This appears to be the first reported instance in which this condition has been diagnosed in life. In a previous study,⁴ the development of congestive failure without apparent cause in a patient with a malignant neoplastic disease was found to be the most important clinical finding pointing to cardiac metastases. Such a condition was present in this patient and, together with the auricular fibrillation, the enlargement of the cardiac shadow by roentgenogram and the pathologic electrocardiogram made the clinical diagnosis of involvement of the heart likely.

This is the second reported instance in which high voltage roentgen therapy has been used in the treatment of involvement of the heart by a tumor. Shelburne and Aronson⁵ have described a patient who suffered from a malignant tumor which had invaded the pericardium and septum of the heart and which was treated with high voltage roentgen therapy. There was strong evidence that the tumor was largely destroyed and that the function of the heart was not impaired by the treatment. An autopsy was not done.

In the case here reported, there also is evidence that the high voltage roentgen therapy was beneficial. There always was subjective and objective improvement following roentgen therapy. Furthermore, the patient lived in a fair degree of comfort for about one and a half years after myocardial insufficiency due to cardiac involvement had appeared. This is contrary to the usual experience, for the refractory character of the decompensation in tumors of the heart has been stressed by many observers.⁶ The fact that the auricular fibrillation was not permanent may have been due to the effects of the irradiation, although this cannot be proved.

The total length of this patient's illness deserves mention. Jackson⁷ concluded that on an average the patient with Hodgkin's granuloma lasts about two and a half years, 75 per cent die within three years and very few survive more than ten years. This patient lived ten and a half years from the time of the original biopsy.

SUMMARY

The development of congestive failure without apparent cause in a patient known to have Hodgkin's disease led to a clinical diagnosis of involvement of the heart. High voltage roentgen therapy seemed to cause improvement, the patient living in a fair degree of comfort for one and a half years after the first appearance of decompensation. Postmortem examination showed extensive involvement of both atria by Hodgkin's granuloma. The heart was normal otherwise.

LYMPHOGRANULOMA VENEREUM OF THE HYPOPHARYNX AND LARYNX

MERVIN C. MYERSON, M.D., NEW YORK

Lymphogranuloma venereum is a systemic venereal disease caused by a filtrable virus and having an incubation period of from three to thirty days. It is characterized by a chronic granulomatous lesion which is generally confined to the anorectogenital region. Occasionally it is found in other parts of the body but rarely in the pharynx or larynx. Lymphogranuloma venereum must be differentiated from granuloma inguinale. The latter begins as an infection of the skin and subcutaneous tissues in which Donovan bodies can be demonstrated and is found almost exclusively in Negroes. On the other hand, lymphogranuloma venereum does not originate in the same structures and is not confined to Negroes.

Buboes of venereal nature were known centuries ago, but it was not until 1913 that Durand, Nicolas and Favre¹ demonstrated that the disease causing them was transmitted through sexual intercourse. Hellerström² stated that the description given by Greek, Roman and Arabian physicians of some

Fig. 1.—Distribution of lymphogranuloma venereum on the soft palate and pharynx.

buboes coincided with that of lymphogranuloma venereum. It was well described by Chassaignac³ in 1859. A dermal sensitization test which bears his name was elaborated by Frei⁴ in 1925. The increase in travel facilities in recent years has played a major part in the introduction and spread of this condition to practically all parts of the United States.

The course of lymphogranuloma venereum seems to depend on the site of inoculation; it follows an acute, subacute or chronic course. The virus exists in human beings as long as the local lesion is present. The primary lesion usually occurs on the external genitalia but may be found on the surface of the skin or in the mouth, throat, rectum or eye. The first manifestation is a small ulceration or herpes-like vesicles on the genitalia. These usually heal in about five days; two or three weeks later, however, the regional lymphatics become involved. This adenitis may subside but usually continues as a low grade process. The glands become matted

Read before the American Laryngological Association in June 1941.

together and may undergo disintegration. At first the skin becomes fixed; this is followed by tissue necrosis, from which fistulas result. The rectum is usually involved late in the course of this disease and becomes strictured as a result of healing. Metastatic lesions may develop at distant points.

When examined microscopically, the tissues display superficial necrosis superimposed on a base of granulation tissue. Epithelioid cells exist in large numbers; plasma cells, monocytes, eosinophilic and neutrophilic polymorphonuclear leukocytes, endothelial cells and occasional giant cells are found in a fibrinous mesh. Sections of glands disclose multiple minute punctate abscesses with peripheral piling up of endothelial cells and reticular cells and an occasional giant cell. The microscopic picture is not easily distinguished from that of syphilis or tuberculosis.

The progress of the disease is usually insidious. Such symptoms as general malaise, headache, anorexia, fever, chills and sweats and local pain are associated with the regional adenitis. The Frei test is positive for from ten to twenty-one days after the appearance of the enlarged glands. The Kahn test may be positive during the early stages but becomes negative. There are cases, however, in which periods of quiescence are followed by periods of renewed activity. The course of the disease in the mouth and pharynx is slow and stubborn, although some cases have been known to clear without even being recognized.

Very few cases involving the pharynx, and practically none affecting the larynx, have been recorded. Lymphogranuloma venereum of the tongue, however, is not uncommon. In the pharynx the disease must be differentiated from other chronic granulomas, such as those caused by syphilis, tuberculosis and fungous infections. The Frei test is the most dependable diagnostic criterion; next in importance is the increased protein content of the blood.

Metastatic lesions may occur in the brain, heart, muscles and other soft tissues, causing symptoms peculiar to the structures involved. About 30 per cent of patients recover from lymphogranuloma venereum without treatment. The disease may last a long time.

Apparently there is no form of therapy that is consistently effective. Brilliant results have been reported after the use of roentgen therapy and drugs of the sulfonamide group. Recently, Kornblith⁵ has reported striking results from the use of sulfthiazole and Frei antigen intravenously.

Fig. 2.—Distribution of lymphogranuloma venereum in the hypopharynx and larynx. Note edematous mass resembling a cyst.

REPORT OF CASE

An American-born Negro woman aged 31, admitted to the service of Dr. Matthew Golden at the Kings County Hospital on Oct. 14, 1940, complained of soreness in the right side

of the throat which had lasted for six months. Her local disease had begun one year before admission, at which time she experienced discomfort in the back of the right side of the nose, and a feeling of fullness in the adjacent ear. She recalled that three months after the onset of her illness she

Fig. 3.—Granuloma characterized by polyblasts, small round cells, plasma cells and reticuloendothelial cells from section of the pharynx. Giant cells are present.

had felt tired and weak and had lost 5 pounds (2,268 Gm.). At the same time she had felt a soreness and swelling of both sides of the upper part of the neck in the region of the angle of the mandible. Her temperature remained about 101 F. She consulted a physician who advised tonsillectomy, which was performed under local anesthesia in December 1939.

All local symptoms disappeared for three months, after which time they returned and persisted until recently. In addition, there have been occasional night sweats, expectoration of blood-tinged sputum and paroxysms of nonproductive cough. Pain has never been a prominent symptom and the patient has never experienced dysphagia. At one time her speech was slightly guttural. She could furnish no information concerning the manner in which the lesion originated. Her medical history was otherwise irrelevant.

Physical examination revealed nothing of significance except the local disease. On the right side the lesion included the tonsillar fossa and pillars, the soft palate, the lateral pharyngeal wall, the nasopharynx, hypopharynx and larynx. In the soft palate it extended as a narrow ribbon along the base of the uvula to the arch of the tonsillar fossa of the other side. The disease process consisted of a diffuse, irregularly distributed superficial, smooth ulcerogranuloma. The entire area was irregularly covered by a thin, film-like, milky exudate. On palpation, the involved structures were firm; they did not bleed readily.

The laryngeal mirror disclosed the same type of lesion in the hypopharynx; in the larynx, however, it was somewhat different. Originating from the aryepiglottic fold, there was a pale, grayish, smooth, firm, cystlike mass about the size of a pecan. It was movable and filled the brim of the larynx.

5. Kornblith, B. A.: Lymphogranuloma Venereum Treatment, in Blumer's Practitioner's Manual, Philadelphia, J. B. Lippincott Company, 1940, chapter 44, p. 511.

so that a view of the vocal cords was obscured. It was pulled into the glottis during forceful inspiration. The cyst-like mass was removed by snare during direct laryngoscopic exposure; it was found to have originated from the posterior border of the aryepiglottic fold. The fold remained as a firm, swollen, grayish structure. The larynx was otherwise uninvolved.

The patient was studied for evidences of syphilis and tuberculosis and, found to be free of them. Her blood cells were normal as to type and number, with the exception of the red cells, which numbered 3,600,000 per cubic millimeter. The Frei test gave a strongly positive reaction. The total protein content of her blood had increased to 9.2 mg. per hundred cubic centimeters and the albumin-globulin ratio was reversed. There was no evidence of active or healed rectal disease such as exists in most cases of lymphogranuloma venereum. Biopsy was performed on the pharyngeal and laryngeal lesions and reported by Dr. W. W. Hala, pathologist to the Kings County Hospital as follows: "Microscopic examination discloses a section consisting peripherally of an epidermoid type of mucosa and beneath is a submucosa, the site of a more or less diffuse granulomatous inflammation. Incorporated in the deeper zones is an area of mucous glands and a small piece of cartilage. The granulomatous lesion is characterized by an intense invasion, particularly by polyblasts, and included among these are small round plasma and larger reticuloendothelial cells.

"There are some areas just beneath the mucosa which appear to be milary pseudotubercles. Throughout the submucosa is a more or less hyaline-like stroma and many of the capillaries are filled with hyaline thrombi. In one of the sections there are typical giant cells simulating the Langhans giant cells of tuberculosis. There are practically no caseous areas, although in some of the hyaline stroma heretofore spoken of the tissue appears to be undergoing necrosis.

"In general, the histologic picture suggests so-called lymphogranuloma venereum."

Roentgen therapy was given without benefit. During six months of observation the lesions seemed to have penetrated slightly beyond the surface.

Treatment with Frei antigen was administered as follows: 0.3 cc. was injected intravenously every three days for two weeks; this was followed by a period of two weeks during which no treatment was given. Three such courses were given.

Recent examination revealed that the soft palate and adjacent structures which were previously tough, firm and ulcerated were now soft and epithelized. The tonsillar pillars, except for the right posterior, which was absent, and the piriform fossa appeared healthy. The larynx presented a healthy, slightly thickened mucosa, especially in the region of the right arytenoid process and its corresponding aryepiglottic fold, where a firm grayish lesion had previously existed.

136 East Sixty-Fourth Street.

ALLERGIC DERMATITIS FOLLOWING EXPOSURE TO TEAR GAS (CHLORACETOPHENONE, CN)

FRANK B. QUEEN, M.D., Major, M. C., U. S. Army
AND

TOM STANDER, M.D., Major, M. C., U. S. Army
CAMP FORREST, TULLAHOMA, TENN.

While we were attending the fourth refresher course (April 1941) at the Medical Field Service School, Carlisle Barracks, Pa., one of us (T. S.) suffered a severe attack of acute dermatitis following a short exposure to tear gas (chloracetophenone, CN) in the course of a routine demonstration of war gases in the gas chamber in which all members of the class participated.

Experienced medical officers assure us that such a reaction is very rare, if indeed not unheard of.

While our present location and duties do not permit us ready access to the literature, and we therefore are unable to cite previous reports of this reaction, it is our belief that a generalized cutaneous allergic reaction to tear gas (CN) is exceedingly rare.

REPORT OF CASE

T. S., aged 43, who had been inducted into the federal service approximately two months before and since April 1 had been a student in the Medical Field Service School, on the afternoon of April 16 passed through the gas chamber containing approximately one tenth the concentration of chloracetophenone that might be expected under field conditions. During the demonstration all students in the class (559) spend about five minutes within the gas chamber, protected by the training mask, at the end of which time they are required to remove the mask and make their way to the exit of the gas chamber about 10 or 15 feet distant. All students were dressed alike in regulation wool shirts and slacks.

Within five minutes after exit from the gas chamber, the patient complained of generalized itching of the skin, which became progressively more severe during the early evening, until by 9 p. m. (four and one-half hours after the exposure) there was diffuse and intense reddening of the skin over the entire body excepting the feet and the portions of the face covered by the training mask. His temperature was 102 F. The following day was spent in severe discomfort because of the itching, although the patient continued his duties as a member of the student officers class. His temperature by that evening had risen to 103 F. The second day following the exposure small blebs 1 to 2 mm. in diameter appeared in many places over the body in moderate numbers. The patient felt ill and very uncomfortable and had no desire for food. The generalized reddening of the skin continued and the temperature remained elevated, varying from 102 F. to 103 F. During this day the patient remained in his quarters.

During the afternoon, severe subcutaneous edema developed over the scalp and forehead, which strikingly altered the appearance of the face, giving it a grotesque, misshapen contour. That part of the forehead not protected by the mask appeared to overhang the orbital ridge, giving the eyes a deeply sunken aspect. Mild generalized edema was apparent in all subcutaneous tissue. Moderate edema of the scrotum developed. The generalized itching of the skin continued, and a mild rash and reddening of the skin appeared on all exposed parts, that is everywhere except the feet and the facial area protected by the mask. By evening there was a severe headache.

Treatment, in the dispensary up to this time, had consisted chiefly of the liberal application of calamine lotion to all affected parts. Because of severe headache and general malaise, the patient was sent to the station hospital, where with general supportive measures, in the course of four days, the signs and symptoms gradually subsided and the temperature returned to normal, although those who knew the patient well did not consider him to be fully recovered until a full month had elapsed. The desquamation of skin, profuse after the sixth day, gradually diminished, though it, too, did not entirely cease until some three or four weeks following the exposure.

Of particular interest in the case is the fact that once before the patient had, on transient exposure by passing through a cloud of tear gas during a course of instruction while in the National Guard, experienced itching of the skin which, though remembered seventeen years after the event, was not incapacitating. (The exposure in this instance was, of course, not nearly so great as that experienced in the gas chamber.)

COMMENT

It is our belief that the case is one of idiopathic hypersensitivity to tear gas (CN) and that it may be considered an allergic type of reaction in all parts of the skin exposed to the tear gas.

We know of but one other case, one of "mild dermatitis," occurring in an officer of the Twenty-Seventh Division, reported to us in a letter from an officer¹ who had also observed the case here reported.

CONCLUSION

The severe subcutaneous edema and desquamation following exposure to a light concentration of chloracetophenone (tear gas) is considered an allergic reaction to the chloracetophenone.

THE USE OF HISTAMINASE BY MOUTH IN PRE-
VENTING SYSTEMIC REACTIONS TO PAREN-
TERAL LIVER EXTRACT

C. B. TAYLOR, M.B., AND D. W. HILGER, M.D., MINNEAPOLIS

The relative infrequency of severe reactions to liver extract is indicated by the fact that there are only 34 cases reported in the literature.¹ The important data on these cases are shown in the accompanying table. In all but 2 instances the preparation was given parenterally. In many of the cases there was no previous history of abnormal sensitivity. That the sensitivity is acquired is indicated by the fact that in nearly every instance reactions occurred only after a number of injections had been given. The nature of the reactions varied from prolonged, generalized urticaria or pruritus to shocklike symptoms. It has been demonstrated (Crip¹) that the sensitivity is to the liver as an organ and not to the general animal antigen. Passive transfer of sensitivity was accomplished in all cases in which it was attempted. One exception to these statements was the case of Milbradt's¹ in which there was sensitivity to the benzene ring

CASE 1.—A woman aged 75 stated that she could not eat beef because it caused her to have nausea and griping abdominal pains. In June 1937 it was proved that she had pernicious anemia and she was given 3 cc. of "campolon"² intramuscularly daily for thirteen days. An oral preparation was then given for several months. In November 1939 she was given 1 cc. of liver extract (exact type unknown) intramuscularly on two occasions without reaction and on May 25, 1940 she was started on 1 cc. of "reticulogen"³ intramuscularly, and this was repeated at weekly intervals until July 25, 1940 and thereafter once a month. After the fifth injection, she complained of severe generalized pruritus and nausea and vomiting. This recurred more severely with each injection, so that in October 1940 she refused further injections. On Jan. 28, 1941, she was admitted to the University of Minnesota Hospital in an extremely weak condition and with a hemoglobin level of only 2.8 Gm. per hundred cubic centimeters of blood. She was given 2 cc. of "reticulogen" intramuscularly without reaction. Ten days later when the patient's hemoglobin was 5 Gm. per hundred cubic centimeters of blood, and she was considerably

compound used as a preservative in the liver extract. Ultimate therapy for these patients has been either discontinuance of treatment if the patient did not have pernicious anemia, substitution of oral therapy or desensitization by gradually increasing doses of liver extract. It appeared that the last method was accomplished in 5 instances.

We have had an opportunity of studying 2 patients who had a strong sensitivity to parenteral liver extract.

preceding days, she tolerated 2 cc. of "reticulogen" intramuscularly without any reaction. Since that time the patient has been given 2 cc. injections on seven occasions when she was taking histaminase orally. She had no reactions. On four alternate occasions when she was not receiving histaminase she was given similar quantities of liver extract, and each time severe, prolonged, generalized pruritus and vomiting developed. There was no eosinophilia.

The "reticulogen" used was extracted from pork livers. Concentrated liver extract⁵ obtained from beef livers caused even a more severe reaction when injected intramuscularly. By intradermal tests the patient was shown to be sensitive to five commercial, parenteral liver extracts whether the animal source was swine or beef. With intradermal tests she was sensitive to beef, swine and chicken liver antigen but was sensitive only to the beef general antigen and not to the general antigen of swine or chicken. This is understandable when one recalls that the patient had a history of allergy to ingested beef. The intradermal tests with substances to which the patient was sensitive were definitely less pronounced when she was receiving histaminase. These reactions were checked frequently, so that we are convinced of their accuracy. It should be stressed, however, that at no time did the administration of histaminase affect the response to intradermal histamine.

On five occasions when the patient was not receiving histaminase the passive transfer of sensitivity for "reticulogen," beef swine and chicken liver antigens was strongly positive. When the patient was receiving the histaminase the passive transfer tests were definitely less positive or negative. Passive transfer was demonstrated for the beef general antigen. Precipitin tests were positive for "reticulogen" and the liver antigens but not for beef general antigen. This is understandable, since the sensitivity to beef is a true atopy while the sensitivity to liver extract and liver antigen is an acquired sensitivity to unusual contact with a foreign substance received by injection. True atopy according to Coca⁶ shows passive transfer but no precipitins, while the acquired sensitivity to foreign substances injected shows both of these phenomena. By quantitative determinations of the degree of flocculation with the Evelyn photoelectric colorimeter, it was strongly suggested that the precipitin test was decreased when the patient was taking histaminase.

CASE 27—A man aged 64 with no previous history of abnormal sensitivity was proved to have pernicious anemia in 1933 and was treated for several months with parenteral liver extract. He had no reactions, but because of his dislike for intramuscular injections he was given oral liver preparations for more than seven years. He was but poorly controlled during this period. In May 1941 he was started on 1 cc. injections of concentrated liver extract³ because oral therapy was not maintaining his hemoglobin and red blood cell count at a satisfactory level. Within ten minutes after the first injection severe generalized urticaria developed. This persisted for more than an hour in spite of treatment to relieve it. On five succeeding injections similar attacks occurred. On two occasions when he was taking oral histaminase he had no reactions. By intradermal tests he was shown to be sensitive to the liver as an organ and not to the general animal antigen. He differed from the first patient in that he had no atopic sensitivity. The intradermal reactions to liver extract were sharply reduced or negative when he was taking histaminase. The reactions to precipitin tests were positive for the liver extract and liver antigen but not for the general antigen of the animal source.

SUMMARY AND CONCLUSIONS

1. Two patients with pernicious anemia acquired severe sensitivity to parenteral liver extract.
2. The oral administration of histaminase for two days before and on the day of injection completely prevented the systemic reactions to the parenterally administered liver extract.

5. Lederle Laboratories, Inc.

6. Coca, A. F.; Walzer, Matthew, and Thommen, A. A.: *Asthma and Hay Fever in Theory and Practice*, Springfield, Ill., Charles C. Thomas, Publisher, 1931.

7. Dr. Phillip Hallock gave us his permission to study this case.

3. Definite, temporary reduction of the intradermal sensitivity to liver extracts followed the administration of histaminase. This was not true for the histamine sensitivity, however.

4. The passive transfer of sensitivity to the liver antigen became much less noticeable following histaminase.

5. We feel that a method by which the liver extract can be administered parenterally in therapeutic doses, as was done in the cases reported, has definite advantages over the previous methods of attempting to solve the problem of acquired sensitivity to liver.

The National Committee for Resettlement of Foreign Physicians was organized¹ more than two years ago to deal with one of the problems that have arisen out of the present European upheaval. Its name is self explanatory. Its objectives were few but vital:

1. To evaluate the eligibility of individual émigré physicians to practice medicine in the United States.
2. To assist those who were found competent in preparing for examinations and for American medical requirements.
3. To further their resettlement in those parts of the United States where medical services are needed.

The task has not been made any easier by the opposition which has arisen in certain quarters. Where once a medical degree from any noted European university was considered proof of outstanding scholarship, now there is a deplorable tendency to swing in the other direction. In incomprehensible isolation, legislators and others build bars around their own small domains, arbitrarily cutting off those valuable immigrants whose professional ability could contribute to the health of the whole nation. It is not the European physician who has changed; it is, at least partially, the American attitude. It is not the universities which they represent which have changed, except in the years since the Nazis have crushed culture in one European country after another. This reversal of attitude has become a major problem to the committee and hampered its work.

For further information, apply to Harry D. Biele, Secretary, National Committee for Resettlement of Foreign Physicians, 165 West 46th Street, New York.

1. Edsall, D. L.: *A Program for the Refugee Physician*, J. A. M. A. 112:1986 (May 13) 1939.

In its activities the committee has been conscious of its responsibility to the nation as a whole, to the profession and to the individual men and women involved. There is involved here a human problem that cannot be overlooked by members of a calling dedicated to the alleviation of mental as well as physical suffering.

We have been alert to the need for protecting American physicians from the possibility of unfair competition by émigrés. This involved careful planning and a long-range program of education of the refugees. The objective was the complete integration of the émigré physician to the American scene.

We recognized the great need for adequate medical service in many rural communities. And the apparent lack of interest in these areas among American physicians is giving us an opportunity to settle these physicians where they are really needed.

American medicine has already profited by the accomplishments of many of the recent immigrants who were given a chance to resume their work: Schindler (Chicago) in gastroscopy, Bergmann and Schoenheimer (New York) and Thannhauser (Boston) in metabolism, Witebsky (Buffalo) in hematology, and others.

ACTIVITIES OF THE COMMITTEE

The starting point for our own work was to set up committees and voluntary boards to evaluate the qualifications of registrants. At present the national committee is composed of state committees in Massachusetts, New York, New Jersey, Maryland, Connecticut, Virginia, Missouri, California, Colorado and Texas; cooperating groups or agencies are located in Louisiana, Tennessee, Minnesota, Ohio and Pennsylvania. State committees embracing the nine Pacific Slope states are

now in the process of formation. From each of the state committees several physicians were chosen to serve on the national committee.

Within each state the special committees act as advisory groups to the émigré physicians and cooperate with state licensing boards and local medical societies. They also locate rural opportunities and internships, and they evaluate individual émigrés considered for placement in practice or institutional work.

The New York State Board of Medical Examiners requires that candidates possess first citizenship papers and have passed an English examination. To exclude unfit persons from committee assistance it was the policy of the national committee in New York to require proficiency in English and a favorable professional evaluation by its advisory committee composed of American physicians, as well as approval of credentials by the New York Board of Medical Examiners.

For New York, where the concentration of émigré physicians is so great (about fifteen hundred in practice and fifteen hundred unlicensed), the national committee has adopted new rules in an attempt to relieve the pressure on the state board of examiners. At least one year's American internship is now required. All registrants who are acceptable for examination by the

National Board of Medical Examiners are required to take this examination if they ask sponsorship of the committee.

STATISTICAL ANALYSIS OF COMMITTEE REGISTRANTS

In 1939 we² had looked forward to a decline in medical immigration. Instead, with the advent of the World War medical immigration remained at a high level in 1940. The total immigration from 1933 through 1940 is shown in table 1. It is equivalent to the total number of graduates in a single year from our own schools.

Approximately 85 per cent of the émigré physicians are male, 15 per cent female. The sectarian proportion remains approximately the same as previously reported, namely 60 to 75 per cent Jewish, 40 to 25 per cent Protestant and Catholic (table 1).

Tables 2, 3, 4 and 5 showing age, nationality and educational background for a group of two thousand one hundred foreign physicians among the four thousand registered with the National Committee for the Resettlement of Foreign Physicians may be considered representative of the entire group of émigré physicians in the United States. Most of these physicians are in the "middle years," looking ahead to many years of professional service (table 2).

² Edsall, D. L. The Emigré Physician in American Medicine, J. A. M. A. 114: 1068 (March 23) 1940

Within the last year, many qualified practitioners have arrived in this country from such nations as the Netherlands, Belgium, France and Norway (tables 3, 4 and 5).

As indicated in table 5, about half of the émigrés are interested in general practice. If those listed as intern-

ists are included, three fifths of the newcomers are available for this purpose. In addition, retraining specialists for general practice is consistently encouraged by the committee, particularly in the case of the younger men.

RESETTLEMENT

Seven hundred men and women have been located in American hospitals throughout the country: less than twenty-five complaints have been received regarding the physicians so resettled. From among the hundreds of physicians established in practice, only five have had to be relocated, and complaints have been made concerning only three. Occasional rumors of unethical conduct in practice have been brought to our attention, but in the great majority of instances investigated no proof has been obtained.

We find that the émigré physician who makes good and is accepted by the community and the medical fraternity is soon assimilated. But—and this is a sad reflection on our own outlook—if one émigré arouses attention by any single act, he frequently becomes the target of whispered, unfriendly and greatly exaggerated rumors which cause other émigrés to suffer stigmatization. Much gossip and false generalizations can be traced to prejudice, unfriendliness and an unwillingness to make allowance for the period of adaptation and assimilation necessary to transform an immigrant into an American.

During the process of sponsorship and resettlement, every effort is made to provide the émigré physician with facilities which will enable him to make a more rapid adjustment to American social conditions. The National Refugee Service, the American Friends' Service Committee and other agencies aid in the linguistic and cultural training of the émigré physicians. Special emphasis is placed on the preparation for general practice in the small communities.

When found suitable for sponsorship, émigrés are recommended for retraining in American medicine by placing them in internships. To date the committee has placed seven hundred émigrés in internships. (Many others have found such places without us.) Men found fit for practice after licensure have been carefully interviewed and, on the basis of recommendations by the advisory board, they have been settled in localities examined in advance. No physician has been placed without the approval of local authorities in a selected

community. To date, about five hundred physicians have been successfully resettled in small towns or villages in New York, Ohio, Illinois, California, Colorado, Maryland, New Jersey and Virginia. Some diplomates of the National Board have been placed in Maine, Washington, Kentucky and Utah.

Recently the committee sent a field secretary on a trip through New York State to visit émigré doctors in their new homes and to report on the progress of their assimilation. After interviewing forty physicians settled in small communities, he concluded:

Assimilation of a foreigner may be said to be complete when he is "in" as well as "of" his community. It may be said with assurance (for there were only two deviations) that in this group assimilation varies inversely with the size of the community—it is nearest completion in the villages, less so in the towns and least so in the cities.

The two principal factors in these doctors' progress are their skill and their social adjustment. Almost all the foreign doctors are—within their varying environments—earning their way modestly. Some communities are enjoying better medical service than they ever had before—small villages from which previous doctors had moved, and farming areas with few physicians, some aged. For it is in these districts that the new doctors are, with the least dislocation of other established practices, rendering the best service.

There are many evidences of acceptance in rural areas. Several alien doctors are members of local fire departments; one is on the state police list for calls in highway accidents; several are members of the local Grange and Rotary club; and a number of wives are members of local women's organizations and church groups.

It is also clear that prejudice is a less hindering factor than competition. Resistance to the establishment of a new practice is not felt alone by aliens (Jewish or non-Jewish), especially in towns where the established doctors have formed a protective clique; disapproval and sometimes open hostility may be the fate of the newcomer, whatever his origin.

There have been, from time to time, "spy scares" involving the foreign doctors. One refers rather ruefully to the "crisis" he passed through last winter; another has heard reports of whisperings about his practices—principally that he is dispensing a slow-acting poison (!) in his pills. Both have emerged from these difficulties by attending conscientiously to their work.

If they are to remain in rural localities, it is essential not only that the doctors be adjustable to our way of life and our medical practices but also that their families fit into the pattern of the community. When one doctor says smilingly "my wife

has more callers than I" and another says "there's my best ambassador," as his little daughter enters the room, and a doctor's wife says "my son is out with the gang all day, he only comes in to eat," and another doctor's wife gets well into a tennis tournament in which she is the only woman, and the Progress Club elects a lady very recently of Berlin—then these families are well on the way to being good normal American citizens. This is in the best American tradition and it is not surprising. Are they any less desirable as fellow citizens

‡ Estimated 1937 Census

then the unselected millions who used to pour into our country from every section of Europe? They should be more so, for they come with professional equipment at a time when every agency of government is clamoring for the very services they can render. Many have come to us after years of successful urban practice or institutional service; some are experienced specialists; the wisest of them are settling into the simple routine of the country practitioner; these are very humble and very grateful

In line with the committee's policy, the experimental program which is operating in Virginia this year provides an example of carefully planned resettlement. In that state some candidates sponsored by the national committee after previous examination by its New York division and the Virginia committee are being permitted to take the medical examinations by special agreement with the Virginia Board of Medical Examiners. The number of rural communities short of physicians determine the number admitted to the examination, and successful candidates are being resettled in the chosen communities.

This committee is not unaware of its limitations. It is not a legal agency and its service is advisory. It realizes that in large groups of émigré physicians there would be unfit as well as qualified persons and within the limits of its capacity it has endeavored to exclude those proved to be incapable. Among the reasons for exclusion are the handicap of advanced age, the limitation of opportunity for certain specialists, inferior ability as indicated in failure in examinations, inadequate medical training, language difficulty, serious physical handicaps, mental difficulties or failure to cooperate with the committee's program. In the period from July 1, 1940 to Aug. 1, 1941 more than one hundred and eighty physicians have been taken off our rolls for various reasons and advised to find other occupation. Wherever possible, refraining in some other field was offered through cooperating agencies.

INADEQUATE NUMBER OF PHYSICIANS

There is developing out of the present national emergency an increasingly acute need for physicians. The Office of Production Management and other federal agencies, for example, estimate that within the next six months or a year there will be a 10 per cent decrease in the number of physicians available for civil wants. The possibility of using qualified émigrés has been recognized by the House of Delegates of the American Medical Association, which recently recommended that its Committee on Medical Preparedness seek to work out a plan to utilize the services of foreign physicians wherever they are needed.

The needs of the Army and Navy are so great that some agencies have urged medical schools to increase their enrolment for next year. The noncitizen émigré is not eligible for military service as a commissioned officer in the Medical Corps, but some have been drafted and are serving with the armed forces. The shortage of physicians is obviously becoming more acute as the Army and Navy call up more men. At the same time the requirements of defense production centers have increased as population shifts have taken place to meet the increased demand for labor.

Recently it was announced that the British government requires about one thousand physicians for civilian and military purposes. Although many émigré doctors volunteered, they could not be accepted because they were not American citizens and were not acceptable to the British government. The same limitations bar their use in the American Red Cross.

PRESENT NEEDS

Apart from the immediately emergent situation there is an older problem. In its efforts to resettle émigrés the committee has sought out the communities where physicians were needed. Its field secretaries in contact with state boards, hospitals and public health agencies have located many places eager to employ any qualified physician in rural communities.

While the general population of the United States has increased, the medical census has not kept pace. Taken by states, there have been some remarkable changes in the past thirty-five years, as indicated in table 6, comparing the individual states as to population and the number of physicians in each as cited in the American Medical Directory in 1906 and 1940 (table 6). Although the population has increased in every state, the number of physicians has fallen in thirteen—in some as much as 30 to 50 per cent.

The committee knows no standard of reference to determine the ideal ratio of physicians to the population. Variables such as area, population, density, per capita income and professional and cultural advantages all play a role.

However, it is obvious that there are many states with too few physicians for their population. In eighteen the ratios range from 1 physician to 901 persons to 1 physician to 1,532 persons. These states include the ones which have had the greatest decreases in the ratio of physicians to population during the past thirty-five years. Only four of these states have had an increase in the number of physicians in relation to the population (South Carolina, North Carolina, Utah and Virginia) but this has been less than 10 per cent in each. These are largely rural communities where medical service is time consuming and costly (charges are often made for mileage involved in each call). Of necessity, medical service is relatively inaccessible. Yet, despite the obvious need, only Virginia and Tennessee have not restricted the settlement of qualified physicians who have been educated abroad. This applies alike to citizens or bona fide immigrants with first papers. In addition to these eighteen states, sixteen others have steadily suffered decreases in the relative proportions of physicians to the general population.

The steady shift in the location of young American graduates from rural to urban areas was shown by Mayer and Harrison³ in their study of the distribution of physicians in the United States. In 1906, 29.4 per cent of the graduates of 1901-1905 had established themselves in cities with populations over 100,000. In 1923, 51.7 per cent of all those who had been graduated between 1916 and 1920 settled in such localities. And the general proportion of physicians in cities over 100,000 increased from 37.9 per cent in 1923 to 46.2 per cent in 1931. Despite the fact that nearly half of the United States population lives in communities with a population of 5,000 or less, the flow of physicians into cities was such that in 1931 less than 20 per cent of the 1920-1925 graduates settled in such places.

In the territories under the jurisdiction of the federal government, the shortage of physicians is acute. Puerto Rico and Alaska both contain a fairly large population of persons who are wards of the government. In the Indian territories the Medical Service has been understaffed for years while the Indian population has been growing at the highest birth rate registered anywhere in this country. The Department of the Interior has recognized this problem and as an experiment this year it has accepted seven carefully selected émigrés as volunteer assistants in hospitals in the Indian territories. If this experiment works successfully and men are available, it may be extended in the future.

ÉMIGRÉ RESTRICTIONS

There is no doubt, therefore, that we are facing an increasing shortage of native physicians. Despite this and despite the unquestioned ability of most refugee physicians to fill it, there is a complex network of legal or semilegal restrictions which stands in the way. Unfortunately, discrimination against the licensure of legally admitted émigrés has increased in many states during the two and a half years of the committee's operation. This discrimination had contributed directly to their congregation in New York, in Boston and to a lesser degree in Chicago, San Francisco and Los Angeles—communities where they have had some chance to do useful medical work and maintain some kind of professional status.

Four types of rulings, or legislations, serve to bar émigré physicians from pursuing their professional careers, even though they are in the process of becoming citizens. These are:

1. The statutory law, or administrative ruling by the state licensing boards, requiring citizenship before admission to a licensing examination.
2. State board rulings which exclude graduates of foreign schools on the ground that there is insufficient information concerning the mode of education and quality of instruction in those schools.
3. A law recently passed in California which denies licensure to all graduates of foreign schools unless the country in which the school is located engages in international reciprocity with American licentiates.
4. The restriction (usually by state board ruling) requiring graduation from an approved American school before admission to the state licensing examination.

Certainly the ultimate attainment of citizenship is highly desirable, but no law or administrative requirement should work to the detriment of the prospective citizen or the community. It is short sighted to retard assimilation and Americanization by barring an otherwise bona fide immigrant from the pursuit of his professional career for five years. The result is liable to be deterioration as a doctor through nonpractice and loss of morale. The New York State law (adopted by a few states) which requires first papers before licensure, and revocation of the license if full citizenship is not obtained within ten years of its issuance, is a model which all the other states might well follow.

Because of new efforts to bar alien physicians by requiring full citizenship, let us consider the validity of some of the arguments for such restriction. One is that, since a practicing physician has as his responsibility the life and well-being of his patient, such a calling with its high degree of personal responsibility should not be entrusted to an alien. Another is that an alien physician might be more likely to perform illegal operations than a citizen physician. Some also argue that, since a physician prescribes narcotics and may be called on to assist in the administration of public health and quarantine law, some activities in the practice of the profession approximate the holding of public office. This thinking confuses administration of law with observance of its provisions. The physician, unless he is appointed as a quarantine officer, has no police authority over enforcement of public health laws. His duty is simply to obey their provisions after he has been instructed in them. If an alien physician is in the process of becoming a citizen there can be no doubt of his personal or civic responsibility.

3. Mayer, L., and Harrison, L. V.: *Distribution of Physicians in the United States*, New York, General Education Board, 1924.

Many states permit licensure for physicians who have declared their intention to become citizens. The United States Supreme Court has pointed out⁴ that "the rights, privileges, and duties of alien declarants . . . differ substantially from those of nondeclarants." These distinctions are even more apparent in the case of the political or religious refugee who, because of legislation in his native country, has become "stateless."

The notion that the alien physician has any other allegiance that may influence his observations of law has no basis. Under existing statutes⁵ he is now equally liable to regular military duty as any native or naturalized citizen. That he cannot be used in the Medical Corps is surely no fault of his own. In the committee's experience, most émigré physicians would be glad to serve in that way, and the Army or Navy could use their services. They might profit from the special knowledge of those experienced in German or other European military medical methods. In other words, the immigrant doctor, obeying the law, is prevented by that very law from playing his full part in national defense. The obvious conclusion here is that some way ought to be worked out which will allow him to do so.

The United States Supreme Court has recorded⁶ a principle for all law makers to remember:

The courts are not bound by mere forms, nor are they to be misled by mere pretenses. They are at liberty—indeed, are under a solemn duty—to look at the substance of things, whenever they enter upon the inquiry whether the legislature has transcended the limits of its authority. If, therefore, a statute purporting to have been enacted to protect the public health, the public morals or the public safety has no real or substantial relation to those objects, or it is a palpable invasion of rights secured by the fundamental law, it is the duty of the courts to so adjudge, and thereby give effect to the Constitution.

In a stirring message, Governor Dwight Green has recently vetoed a series of bills sponsored in Illinois which would have required citizenship for licensure in medicine and other professions. The Attorney General⁷ also ruled that the bills were unconstitutional and violated the fourteenth amendment to the United States Constitution. For a complete statement of the case against such laws, Governor Green's message can be quoted:

The Illinois laws and regulations concerning regulation for and practice of medicine exact high qualifications from those who seek their privilege, and those who enforce these regulations are fully competent to determine the attainments of every applicant.

If there are those who are unqualified to practice medicine, this is determined as it would be in the case of any citizen applicant. When those who apply are found qualified, however, we are given the advantage of their skill and this advantage is gained at a time when national preparedness through the induction of great numbers of men in our professions has depleted the number of those available for home service.

In more than half the world, the forces of oppression and totalitarianism are at war to destroy the principles of free democracy. This nation still stands forth as the one in which the rights of the individual to sustain himself by his own efforts are guaranteed. I do not believe that this is the time at which to weaken, or withdraw, that guaranty of freedom and opportunity.

4. *Porterfield v. Webb*, 263 U. S. 225; *Webb v. O'Brien*, U. S. 313; *Frick v. Webb*, 263 U. S. 326.

5. *Terrace v. Thompson*, 263 U. S. 197; 218 Act of Aug. 31, 1918, chapter 166; 40 Stat. 76, 884, 955.

6. *Mugler v. Kansas*, 123 U. S. 623, p. 661.

7. The attorney generals of South Dakota in 1926, of Texas in 1939 and of Utah in 1939 also held such legislation to be unconstitutional.

Many unfortunate but meritorious people have been driven from their homes and places of employment to seek such freedom as is granted under our constitutional form of government.

Many of them are persons of high professional attainment. There is little likelihood that any of them would become a charge upon the state. The State Department of Registration and Education estimates that there are now two hundred and twenty-eight applications by aliens pending for licenses in various occupations and professions and of this number one hundred are from physicians.

Neither is there a probability that they would not welcome the opportunity, as soon as it was legally available, to become naturalized citizens of the country in which they have sought the right of liberty.

A great many American born men and women who stand highest in our professional and business life are directly descended from those of alien birth who similarly sought liberty and safety in this country generations ago. Had our states, or national government, denied freedom of opportunity to them, this nation would have been deprived of many of its worthiest citizens of today.

It is in a time such as this that official and personal relations should be conducted upon the most liberal interpretation of liberty.

There is another type of restrictive action based on the allegation that there is insufficient information to determine the reputability and good standing of medical schools in foreign countries. Resolutions along these lines have been introduced within a few months of each other in the Illinois Medical Society⁸ and the New York State Medical Society⁹ using virtually the same language. They recommend that recognition for medical licensure in the respective state, whether after examination or otherwise, and irrespective of the question of citizenship of all graduates of medical schools located in the United States and Canada. Any other method of recognition is held as constituting the grossest type of discrimination in favor of foreign graduates. In New York this resolution, if made effective, would apply to candidates in the future. In Illinois the resolution went further and required that the inspection of the foreign schools be made expressly at the invitation of those schools and that the cost of the inspection should be defrayed by the foreign schools. Obviously, the latter requirement would seldom, if ever, be met by the Nazi rulers now in control of Europe's universities. These resolutions make no reference to the quality of instruction in any of the foreign schools, thus lumping together universities like Cambridge, Oxford, University College of London and the Universities of Munich, Freiburg and Berlin with less reputable schools.

An editorial in the *Connecticut State Medical Journal*¹⁰ says of this resolution:

The Illinois State Medical Society, while it admits the physical impossibility of determining the standard of foreign medical schools, requires that the admittedly impossible be done before graduates of foreign schools be admitted to practice. It would appear to us that this imposes an undue hardship on many reputable and desirable doctors who have trained in foreign schools. As long as it is so difficult to appraise foreign schools it would seem that the fair thing to do at this time would be to lay the stress of admission on the examination of the candidate both as to character and professional ability. Insistence that the candidate be a citizen of the United States, a matter previously discussed in this journal, while perhaps something of a hardship because of the residency

8. *Illinois Bans Graduates From Foreign Medical School*, editorial, *Illinois M. J.* 79:272 (April) 1941.

9. Report of Reference Committee on New Business & Licensure—Standards For Recognition of Foreign Medical Schools, Minutes of the Annual Meeting of the House of Delegates, New York State Medical Society, New York State J. Med. 41:1381 (July 1) 1941.

10. *The Foreign Graduate*, editorial, *Connecticut M. J.* 5:441 (June) 1941.

requirements, seems entirely justified. Interference with the right of a citizen of the United States to practice his chosen profession because he trained in a foreign school would seem both unjustified and unfair.

The deterioration of the continental schools that have come under the Nazi régime justifies barring graduates from such schools after the change, but no one can justify a retroactive ruling which would bar graduates of the leading European schools of earlier years. These resolutions ignore the realities concerning the good foreign schools of the past forty years.

As recently as in 1929 the Council on Medical Education and Hospitals of the American Medical Association stated:¹¹

With the requirements of two or more years of premedical study, medical education in the United States is now on a par with the requirements in other countries. Continuing, the report pointed out that there are three hundred and twenty-one bona fide medical schools in all countries outside the United States, giving a complete list of the schools.

Furthermore, lists of acceptable foreign schools have been compiled by the Royal Society of Great Britain and are used by the National Board of Medical Examiners. Graduates of inferior schools are already barred from taking the examinations of the National Board of Medical Examiners, whose high standards have won reciprocity for their diplomates in more than forty states in this country.

A bill was recently passed in California which would deny the license even to a California native son who happens to be a graduate of a foreign school, unless the country in which the school is located extends reciprocity to Americans. This would bar the foreign educated competent citizen physician, native or foreign born, from California forever. This is indeed chauvinistic legislation of the most deplorable type. How it can be construed to be in the interests of the public welfare is difficult to see.

A further barrier to the equitable distribution of qualified refugees has been created by licensing boards which have withdrawn reciprocity from those states in which émigrés have been admitted to licensure. This certainly cannot be justified in the light of admittedly increasing needs.

In a class with restrictive rulings directed toward applicants for licenses is the deplorable effort in some county medical societies to deny admission to membership of foreign physicians who are licensed. Some have required citizenship; others have ruled that applicants be graduates of class A American schools. Membership in the county society is often necessary for hospital practice and is considered the natural prerequisite to good standing in the medical fraternity. These requirements are degrading to the licensed émigré with first papers who is doing his best to become a reputable member of the whole community. The only reason behind such rulings must be fear of competition or rank prejudice.

Sickness knows no citizenship, and our profession must always stand for a liberal and reasonable policy. We must strive to maintain high tradition which our world has inherited from the past. We know that the basis of all progress in science and learning is through international cooperation. In no other form of human

activity has there been so complete an internationalism as in medical science. If this is true in the scientific realm it should be no less true in the application of the science to the needs of the sick. The tools we use bear the names of every nation and race.

RECOMMENDATIONS

All the new needs for physicians certainly should provide the avenue to a solution of the problems created by the concentration of foreign physicians in New York and in a few other cities. A constructive attitude on the part of organized medicine and a comprehensive resettlement program would greatly serve the public interest.

Many state licensing boards have the power to issue licenses of a temporary or a limited nature. Citizenship at the earliest possible moment may be made a condition of such a license. Some states may even define the areas of practice in which the license may be used. Such regional licenses with proper clauses for revocation should satisfy any skeptic by giving the émigré physicians the test of assimilability and fitness.

By cooperation with the United States Public Health Service and local state agencies, employment of qualified foreign physicians could be arranged in medically needy areas developing out of the national defense program.¹²

The *New York Medical Week*¹³ and the president¹⁴ of the Medical Society of the State of New York have both pleaded for the use of loyal refugees in the defense program. The *Medical Week* comments too:

At the present time there are over 2,500 medical refugees located in this state. They have the qualifications, and many have the desire, to make valuable contribution to the defense program.

So far the government has refused to accept the services of these men. If this policy is continued, we will see the native American physician who serves his country, as all good citizens should, losing his practice to foreign colleagues who are refused the opportunity of similar service. The utilization of loyal refugees in the defense program would help to protect native Americans against permanent loss of their practices as a result of military service. It would also facilitate the assimilation of refugee physicians into American life and give spiritual as well as legal validity to their applications for citizenship.

There is no doubt that some kind of internship training in an American hospital is desirable before licensure of all young men, but justice and wisdom dictate that, in the case of men of middle age and over who have had abundant clinical experience, such a requirement is

12. In reply to an inquiry pertaining to the incorporation of alien physicians into the British defense program, the following communication was received from the British Library of Information in New York City: "The position briefly is as follows: For the first sixteen months of the war, though there was considerable pressure on the government from some quarters to admit alien doctors to work in hospitals or in some form of the national medical services, few were actually employed. One reason was that there was a general ban on doctors or medical students of enemy alien origin entering any hospital which gave treatment or was available for treatment to any members of His Majesty's Forces, and it was not until August 1940 that this ban was removed. During the autumn of 1940 an acute shortage of doctors developed, and a number of members of Parliament pressed for permission to be granted to all adequately qualified doctors to practice, whether they had British qualifications or not. In January, 1941, under the Medical Practitioner's (Temporary Registration) Order, 1941, it was provided that alien doctors with foreign qualifications might be admitted temporarily to the Medical Register. Since that time, applications from alien doctors are considered by the Central Medical War Committee, and, when approved, submitted for scrutiny to the security authorities. Doctors of enemy alien nationality are recommended for employment mainly in hospitals and institutions. On the 12th June 1941 it was stated in the House of Commons, that, apart from those alien doctors commissioned in British or Allied forces, two hundred and eighty-nine alien doctors had been registered under the Medical (Temporary Registration) Order, and cases were examined at the rate of 80 a week."

13. Editorial, *New York Medical Week* 20:4 (Aug. 30) 1941.

not necessary. If the present demands for interns continue, it will be necessary for hospitals to accept much older men than in the past years. Until the present national crisis the committee was able to place only émigrés under 35, but in recent months hospitals have been willing to take men as old as 45 to 48.

There are at least fifteen hundred unplaced physicians who are available to meet increased needs. Many licensed émigrés now forced to practice in cities would grasp the opportunities available in the rural states. Most of them have little or no reserve resources and have eagerly sought any professional opportunities. In view of the success achieved with rural placements, more rural states should be urged to take a limited number each year.

State licensing boards now unable to evaluate European schools should apply the standards of the National Board of Medical Examiners. If this is insufficient they should require that applicants from foreign medical schools pass the examination of the National Board of Medical Examiners. Moreover, a committee should be set up with representatives of the state board of medical examiners, the Council on Medical Education and Hospitals of the American Medical Association and the National Board of Medical Examiners, which could prepare an up to date list of bona fide medical schools, giving the years of graduation which would be acceptable for admission to examination.

SUMMARY AND CONCLUSIONS

1. The National Committee for Resettlement of Foreign Physicians has succeeded in assisting and placing between twelve and fifteen hundred émigrés in internship or practice during the two and a half years of its existence; no serious complaints or maladjustments have occurred among 95 to 98 per cent of such placements.

2. Rural resettlement has been particularly successful in the few states still open to émigrés.

3. Because of increasing natural needs (especially in rural states) and the special needs arising from the present national emergency, ample opportunities exist to employ the unlicensed recent émigrés.

4. Cooperative action by all medical agencies, federal and state, together with the American Medical Association, could provide a plan to redistribute and resettle the qualified émigré physicians.

5. Tests for qualification in the form of state board or national board examination should be applied to all.

6. Younger émigrés (under 40) should be required to take internships before licensure.

7. All licenses should stipulate that the émigré applicant shall have first papers to obtain citizenship as soon as the law permits.

8. Temporary licenses with similar safeguards should be issued after successful examination, for use in selected areas through state licensing boards. Supervisory agencies of the state and the state medical societies should be available to check the work of the temporary licensees.

9. Proper resettlement of the qualified émigrés and the acceptance of some for Army and Navy needs will protect native Americans against permanent loss of their practices, if called to military service. Such action will also avoid overcrowding and undue competition in many cities and will contribute to the medical care of the nation as a whole.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary

EMERSON FEVER CABINET ACCEPTABLE

Manufacturer: J. H. Emerson Company, 22 Cottage Park Avenue, Cambridge, Mass.

The Emerson Fever Cabinet provides a means of producing and maintaining artificial fever. The manufacturer states that while the apparatus is in operation a thermostatically controlled atmosphere is supplied to the chamber in which the patient lies and that 100 per cent humidity may be produced at any temperature, making it possible for a lower cabinet temperature to be used in producing the fever. It is also stated that as far as possible the movement of air in the cabinet has been eliminated, since such movement is a factor in heat loss.

The apparatus is portable and is protected electrically by a 30 ampere fuse. The cabinet is hinged at the foot end; this arrangement is said by the manufacturer to effect an economy in room space and to facilitate moving the patient in or out of the cabinet.

When closed, the cabinet may be locked securely. Two hinged doors located on each side of the cabinet make possible nursing care and the administration of intravenous solutions. The doors serve as shelves when lowered and are curtained to prevent in part the escape of the heated moist air. Electric control switches are located under the head rest out of the patient's view, and two air blowers at the head of the cabinet may be directed to blow on the patient's face. The interior of the cabinet is of stainless steel construction for ease in cleaning.

Emerson Fever Cabinet

All walls of the cabinet are insulated to conserve heat. A large reservoir of water is located in the lower half of the unit, and humidifiers which dip into the reservoir are used to force moist heated air into the upper cabinet during the induction of fever. The reservoir is limited to 150 degrees maximum water heat, and this temperature may be held at the desired level by the adjustment of the thermostat. A rectal thermometer remains in place during the treatment and indicates the patient's temperature at all times.

As evidence of the efficacy of the apparatus the firm asserts: Maintenance of fever is carried out with a minimum of air movement (the only movement of air in the cabinet when the doors are kept closed is the convection currents of heat rising in a closed chamber). This is important, as air movement over the surface of the body is one of the greatest factors effecting heat loss. In most cases fever is maintained with a temperature but a few degrees higher than the desired temperature of the patient. As the temperature at the very top (the hottest point in the cabinet) cannot exceed 116 to 124 F., there is a minimal danger of burning patients.

This cabinet and the previous model have been used for two years with satisfaction. The average induction time does not exceed that of other hyperthermia cabinets in general, average period of elevation to 104 F. has been about sixty five minutes, and to 107 F. two hours. This is the usual time which is provided for the induction of fever.

Patients have been treated for ten hours at peak temperatures of 106.8 F. and all other prescriptions required in fever therapy. By the simple maneuver of jacking up the bottom of the cabinet it is possible, through the shock position, to continue the patient's fever therapy when, under ordinary conditions due to fall of blood pressure, it would have otherwise been deemed inadvisable.

The advantage in this unit is economy in maintaining temperature and the comfort which the patient has during the maintenance period. It takes little heat to keep the patient's chamber balanced at the proper point to hold the patient at the desired level. Very flat plateaus of temperature are obtainable.

In the Council's investigation of the Emerson Fever Cabinet, the apparatus was used in a large fever therapy department and was found to be satisfactory both in raising the bodily temperature of patients and with respect to the patient's comfort. It was possible to produce a high humidity in the cabinet. There was little or no motion of air, and the patients were comfortable during treatment.

The Council voted to accept the Emerson Fever Cabinet for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary

DRISDOL—Vitamin D₂—9||10 Ergostetraene (18 10, 5 6, 7 8, 22 23) ol-3—C₂₈H₄₄O

Vitamin D₂ may be prepared by ultraviolet irradiation of ergosterol in a suitable solvent or by electronic bombardment of the compound. It is not identical with the vitamin D which predominates in fish liver oils and which is called vitamin D₃. A method of preparation of vitamin D₂ is given in Addendum 1936 to the British Pharmacopoeia, 1932, page 20. The crystals have a potency of 40 units of vitamin D (U.S.P.) per microgram. (For methods of assay see U.S.P. XI, Second Supplement, page 136.)

Actions and Uses—Drisdol is used as an antirachitic. For allowable claims, see under allowable claims for vitamin D.

Dosage—Drisdol is administered as drisdol in propylene glycol. Average daily dose, 2 drops dissolved in total ration of modified or whole milk. If administered in water, gruel, etc., 4 drops daily for the average infant, and up to 15 drops daily for the premature or rapidly growing infant. Daily curative dose, 15 to 20 drops. The product is marketed with a special dropper delivering 250 U.S.P. units of vitamin D per drop.

Manufactured by the Winthrop Chemical Company, Inc., New York. U.S. patent 1,902,785, (expires March 21, 1950) and 2,030,792 (expires Feb. 11, 1953). U.S. Trademark 333,661.

Drisdol in Propylene Glycol, 5 cc Bottles. Contains approximately 0.25 mg of drisdol in each cubic centimeter of propylene glycol solution and has a potency of 10,000 units of vitamin D (U.S.P.) per gram. The propylene glycol used in the preparation of this product complies with the standards for propylene glycol N.N.R.

Drisdol in Propylene Glycol, 50 cc Bottles. Contains approximately 0.25 mg of drisdol in each cubic centimeter of propylene glycol solution and has a potency of 10,000 units of vitamin D (U.S.P.) per gram. The propylene glycol used in the preparation of this product complies with the standards for propylene glycol N.N.R.

Drisdol occurs as a colorless odorless acicular, crystalline substance. It is insoluble in water, soluble in alcohol, ether, chloroform, acetone, ethylene glycol and propylene glycol, sparingly soluble in vegetable oils. The melting point of drisdol lies between 115 and 118°C. Solutions of drisdol possess an absorption maximum at 2,640 angstroms.

Dissolve approximately 0.5 mg of drisdol in 5 cc of chloroform and add 3 drops of acetic anhydride and 3 drops of sulfuric acid and shake the mixture, a bright red color develops which rapidly changes to violet, blue and finally to green.

Dissolve 0.05 Gm of drisdol and 0.05 Gm of 3,5 dinitrobenzoyl chloride in separate 1 cc portions of anhydrous pyridine. Mix the solution and warm the mixture on the water bath for ten minutes. Add 5 cc of water, filter and wash the precipitate repeatedly with small amounts of cold water. Recrystallize the precipitated dinitrobenzoyl derivative twice from acetone and finally dry it in a desiccator under partial vacuum. The melting point of the product is from 147 to 149°C. The specific rotation $[\alpha]_D^{25}$ of the drisdol dinitrobenzoate dissolved in acetone + 80 degrees.

Dissolve approximately 0.01 Gm of drisdol in 1 cc of alcohol and add 1 cc of a 1 per cent solution of digitonin in 90 per cent alcohol, allow the mixture to stand for twelve hours. No precipitate occurs (absence of ergosterol).

Dissolve approximately 0.03 Gm of drisdol accurately weighed in 1 cc of acetone at 25°C. Polarize the solution in a 0.5 decimeter tube at 25°C using sodium light. The specific rotation lies between +79.5 and +83.5 degrees. Determine the amount of carbon and hydrogen present in drisdol by burning the substance in an appropriate combustion train, the carbon content should not be less than 84.6 per cent nor more than 85.1 per cent, the hydrogen content should not be less than 10.9 per cent nor more than 11.3 per cent.

NOVOCAIN (See New and Nonofficial Remedies, 1941, p. 81)

The following dosage form has been accepted

Nocean Supracain Solution 1 Per Cent. Each cubic centimeter contains procaine hydrochloride 0.01 Gm, epinephrine bitartrate 0.00001 Gm, sodium chloride 0.004 Gm, potassium sulfate 0.004 Gm. Marketed in 0.5 cc rubber diaphragm capped bottles accompanied by an air vent filter needle.

SULFAPYRIDINE (See New and Nonofficial Remedies, 1941, p. 511)

The following dosage form has been accepted

Tablets Sulfapyridine 0.065 Gm (1 grain)

Prepared by Eli Lilly & Co., Indianapolis. No U.S. patent or trademark.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1941, p. 514)

Sulfathiazole-Endo—A brand of sulfathiazole N.N.R.

Manufactured by Endo Products, Inc., Richmond Hill, N.Y. No U.S. patent or trademark.

Tablets Sulfathiazole Endo, 0.5 Gm (7.7 grains)

Sulfathiazole-Smith-Dorsey.—A brand of sulfathiazole-N.N.R.

Manufactured by The Smith Dorsey Co., Lincoln, Neb. No U.S. patent or trademark.

Tablets Sulfathiazole, 0.5 Gm (7.5 grains)

Sulfathiazole-Lilly (See THE JOURNAL, Aug. 30, 1941, p. 680)

The following dosage form has been accepted

Tablets Sulfathiazole Lilly, 0.065 Gm (1 grain)

Sulfathiazole-Upjohn (See THE JOURNAL, Sept. 20, 1941, p. 1017)

The following dosage form has been accepted

Tablets Sulfathiazole Upjohn, 0.25 Gm (3.83 grains)

SODIUM r-LACTATE ONE-SIXTH MOLAR (See THE JOURNAL, Oct. 25, 1941, p. 1445)

One-Sixth Molar Sodium r-Lactate Solution.—A brand of sodium r-lactate one-sixth molar-N.N.R.

Manufactured by Baxter Laboratories, Inc., Glenview, Ill., and Don Baxter, Inc., Glendale, Calif. (American Hospital Supply Corporation, Chicago, eastern distributor). No U.S. patent or trademark.

One Sixth Molar Sodium r Lactate Solution in Vacoliter Containers. Each 100 cc contains sodium r-lactate 1.87 Gm in sterile distilled water. Also marketed in half size vacoliter containers.

Council on Foods and Nutrition

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary.

FATS AND OILS (See Accepted Foods, 1939, p. 30)

Interstate Cotton Oil Refining Company, Sherman, Texas

Mrs. TUCKER'S SHORTEVING, hydrogenated cottonseed and soya bean oil with added lecithin.

Analysis (submitted by manufacturer).—Moisture, 0.05%, total solids (fat) 99.95%, fatty acids trace, iodine number 80 to 90, melting point 114°F., saponification value 192.

Calories—9 per gram, 255 per ounce.

FRUIT JUICES INCLUDING TOMATO JUICE (See Accepted Foods, 1939, p. 48)

Sunshine Foods, Inc., Lakeland, Fla. (plant at Winter Haven, Fla.), a subsidiary of Pomona Products Company, Griffin, Ga.

SUNSHINE BRAND ORANGE JUICE

Analysis (submitted by manufacturer).—Moisture 89.5%, total solids 10.5%, ash 0.4%, fat (ether extract) 0.1%, protein (N x 6.25) 0.5%, crude fiber 0.01%, carbohydrates other than crude fiber (by difference) 9.4%, acidity as citric acid 0.7%, peel oil 0.008%, pH 3.80.

The firm reports that the product contains from 31.2 to 46 mg per hundred cubic centimeters (624 to 920 international units per hundred cubic centimeters) as determined by the dye method and by iodine titration.

Calories—0.41 per gram, 12 per ounce.

MILK AND MILK PRODUCTS (See Accepted Foods, 1939, p. 230)

Minnesota Evaporated Milk Company, Winona, Minn.

GOLDEN GLOW BRAND EVAPORATED MILK

Analysis (submitted by manufacturer).—Moisture 73.0%, total solids 27.0%, ash 1.5%, fat (ether extract) 7.9%, protein (N x 6.38) 6.4%, lactose (by difference) 11.2%.

Calories—1.4 per gram, 39.8 per ounce.

SATURDAY, NOVEMBER 29, 1941

"PLAIN WORDS ABOUT VENEREAL DISEASE"

On Sunday morning November 16, newspapers which subscribe to the North American Newspaper Alliance published a copyrighted article written by Paul de Kruif heralding a forthcoming book by Drs. Thomas Parran and R. A. Vonderlehr entitled "Plain Words About Venereal Disease." De Kruif said that in their new book these authors "tell the story of how between one and two million of our young men, who were brought—free of venereal disease!—into the new army, are now being needlessly exposed to time-wasting gonorrhea and life-endangering syphilis, because the War Department and municipal authorities have seemed not to think it important to apply the powerful preventive measures that Secretary of War Newton D. Baker and Gen. John J. Pershing used—with brilliant success—in World War I, twenty-four years ago." After reviewing the campaign against venereal disease waged by Dr. Parran since he became Surgeon General, de Kruif points out that those rejected by the Army because of venereal disease are thrown back into civilian life and are not the army's business. And he proceeds "But it was definitely the army's business to see to it that its now more than a million of young men, all of them, venereally speaking, clean as a hound's tooth, should be kept that way." He points out that venereal disease rates fell in the Army at first because of the dilution brought about by a great increment of men free from venereal disease. However, he proceeds "Now, as of June 1941, the gonorrhea rate has shot up from 27.7 to 40.3. And the syphilis rate is rapidly climbing back up to the premobilization rate. . . . This can lead us to one terrible conclusion: that scores of thousands of soldiers are now being infected in the vice dives around the Army camps." In contrast to this statement of de Kruif, presumably based on the book, a release by the War Department, November 14, states that "In 1917, the annual rate for all venereal diseases was 107 in 1,000 soldiers. In 1918 it was 90 per 1,000. The present annual rate approximates 40 per 1,000. The annual rate for syphilis in the Army was 17.56 per 1,000 in

1918. This rate dropped progressively to 6.59 in 1939, 5.7 in 1940 and in August 1941 it dropped to 5.5." Moreover, a statement made by Mark S. Watson in the *Baltimore Sun*, November 16, says "The de Kruif statement that the gonorrhea rate alone had soared from 27 to 40 per thousand is not supported by the figures so far studied in the Medical Corps' detailed report." Perhaps these discrepancies in figures are explainable. The Army Medical Department may well resent charges based on exaggerations. There seems to be every reason to believe that the venereal disease incidence in the Army is steadily declining. That, however, is not the main issue raised by the Parran-Vonderlehr book.

The chief issues raised by the de Kruif advance publicity and by this book itself is the charge that the Secretary of War has been lax. To quote the book itself (p. 81):

Infections do not occur in the camps. The source of all venereal infection lies in the civilian population. It follows that the protection of soldiers, sailors and defense workers from syphilis and gonorrhea is a civilian responsibility. It is a responsibility which civilians could be organized to carry with less difficulty if the Secretary of War would take a leaf from the book of Secretary of War Newton D. Baker.

The thesis of the Parran-Vonderlehr volume is that the May act, passed in July 1941, ought to be made fully effective. "Under the provisions of this Act," to quote the book (p. 88), "It is unlawful to engage in prostitution, to aid and abet prostitution, to keep a house of ill fame, or to rent or permit the use of a vehicle or building for that purpose within such areas around military and naval establishments as the Secretaries of War and Navy may designate in order to protect the health and welfare of the forces. The Federal Bureau of Investigation is responsible for its enforcement." Then the book charges (pp. 89-90) "The plan on paper is perfect. Already some ground gained has been lost. Unless vigorous Federal action is initiated, we may sink to the level of France in our tolerance of prostitution." This charge is further explained (p. 118): "The May Act comes into the picture in that it gives the military commanders the power of initiating action where local interest centers more in the exploitation of the soldier than in the desire to keep him fit to fight."

Now the phrases that have been quoted must be examined in the light of what has actually occurred since the May act was passed in July 1941. In the first place the chief of staff, G. C. Marshall, by order of the Secretary of War, issued circular 170 on August 16, 1941. This circular says:

II.—*Prohibition of prostitution within reasonable distance of Military Establishments.*—The following procedure is prescribed in order to carry out effectively the provisions of the act of Congress approved July 11, 1941 (sec. I, Bull. No. 23, W. D., 1941):

1. The commanding officer of each post, camp, or station is basically responsible for determining if and when prostitution in areas adjacent to the military reservation adversely affects

the efficiency, health, and welfare of the personnel of the post, camp, or station. Initially he will enlist the efforts of the local civil authorities to remove such prostitution conditions.

2. If such local cooperative measures are not effective, the local commander will make written request to his appropriate

personnel at the specified post, camp, or station, the Secretary of War shall designate and publish in the War Department orders the specific area or areas adjacent to or a limiting zone around the post, camp, or station where it shall be unlawful to engage in prostitution or otherwise aid or abet same as described in the Act of Congress referred to above (A. G. 250.18 [3-12-41]).

This circular letter is obviously the due form in which the Army may cooperate with the intent of the May act. No mention of it is made in the Parran-Vonderlehr book or in the de Kruif exacerbation. Perhaps they did not know of it—perhaps the book had gone to the publisher before it was promulgated. However, the United States Public Health Service is a part of the Federal Security Agency. True the administrator, Mr. Paul McNutt, who is also Director of Defense, Health and Welfare Services, has issued a statement to the effect that he did not see the book until the day when the public release by Paul de Kruif appeared. Nevertheless, both the Administrator and Dr. Parran must have been familiar with a statement issued by the Adjutant General of the War Department on Oct. 2, 1941 (A. G. 353.8 [9-13-41] MB-A-M.) on the Establishment of the Division of Social Protection by the Federal Security Agency. "The first task of this Division

corps area commanders for a special report of prostitution conditions in the specific area adjacent to the post, camp, or station. Such requests will be referred to the Defense Regional Coordinator of the Federal Security Agency who, under existing arrangements, will cause a special investigation and report of conditions to be made. The Regional Coordinator's report when received by the corps area commander will be referred to the local military commander for his information.

3. If the Regional Coordinator's report transmitted through the corps area commander to the local commander contains factual information of the existence of prostitution, the local commander will again consult the local authorities, inform them of the general contents of the report, and advise them of the action in paragraph 4 which he will be required to take if the unfavorable conditions are not corrected.

4. If the local authorities fail to take corrective measures within a reasonable period of time after they have been informed of the content of the report, the local commander will forward a letter to the Adjutant General, through military channels containing the following:

(a) A statement of prostitution conditions which are inimical to the efficiency, health and welfare of his command, based upon the Regional Coordinator's report.

(b) A narrative of the efforts which have been made to cause the local authorities to correct conditions.

(c) A recommendation as to the specific area or areas which the Secretary of War shall publicly announce.

5. If the report indicated in paragraph 4, together with other available information, indicates the existence of a condition harmful to the efficiency, health, and welfare of military

is to promote the public health by the reduction of venereal disease through the repression of commercialized prostitution" says this statement. The announcement (published in full elsewhere in this issue) is

epoch making in the principles it emphasizes and the technic it proposes. Most important is the following paragraph:

4. It is the policy of this Division to work through State and local authorities. It is the hope of those responsible for the administration of this program that the repression of commer-

cialized prostitution will continue as a *permanent policy* throughout this nation after this emergency is over. This can be accomplished only when State and local authorities and local communities are convinced that repression rather than toleration is the answer to the problem. It is, therefore, the responsibility of this Division to bring about the voluntary adoption of its program by local authorities as a permanent policy. The establishment by military authorities of areas as out of bounds for men in uniform, or the invocation of the May Act, are measures to be taken only as a last resort. Experience in the last war, and the attitude of Federal and local authorities to date in this emergency, all point to the likelihood that our program can be established in most defense areas on a voluntary basis.

This statement also both the Parran-Vonderlehr book and the de Kruif publicity ignore. Yet these official statements are far more in accord with the American tradition than that point of view which would federalize the pursuit of the prostitute in a program for the control of venereal disease. Indeed, this attitude toward more and more federal domination of state and local health activities becomes the focal point of this consideration.

If noninfected selectees are becoming infected, the matter is well worthy of public concern. But does the answer lie in more money to be spent on venereal diseases? The book emphasizes (p. 148) that "State expenditures for venereal disease control this year range from less than \$0.005 per capita in Nebraska to \$0.12 in Maryland." And the book continues (p. 149): "To do this job necessitates an increase of 75 per cent in present facilities, and at least \$10,000,000 annually in Federal funds, beginning now, to extend and improve work already begun against syphilis but which has hardly been started against gonorrhea."

When the de Kruif article was published and when Walter Winchell said over the radio on the same night that this scandal would shake many in high places, the dirty linen was tossed into the public laundry. The effect on the morale of the official personnel in many Washington bureaus was all that the scandal mongers might have hoped. For some days the gossips have been mouthing this morsel with relish. By the available evidence the charges were perhaps not too well founded, the situation not fully reflected, the remedies proposed—(a) continence for the soldier, (b) federal control of prostitution, (c) increased federal appropriations for venereal disease—none too certain in their curative effects and possibly harmful to the body politic.

Meanwhile the Army Medical Department, confident that it is exerting every effort to make its control program effective, lists this outline of its procedures:

(a) Physical examinations to prevent the induction into the service of selectees infected with venereal diseases.

(b) Education of the soldiers concerning the dangers of venereal diseases, and advice as to the desirability of continence.

(c) Provision of prophylactic facilities for those who expose themselves to the risk of infection.

(d) Regular monthly physical inspection of troops to detect infected individuals.

(e) Thorough treatment until all men who become infected are cured.

(f) Isolation of venereal disease patients during the infective stages.

(g) Disciplinary measures for soldiers who become incapacitated because of venereal diseases, unless innocently acquired.

(h) Cooperation with the Bureau of Medicine and Surgery, U. S. Navy; the U. S. Public Health Service; the Division of Medical Sciences, National Research Council; the American Social Hygiene Association, etc.

(i) The reporting to the responsible civil health authorities of known civilian sources from which soldiers are infected, in order that such sources may be traced and eliminated.

(j) The agreement with the U. S. Public Health Service whereby the latter, working through state and local agencies, has undertaken to eliminate civilian sources of venereal infection in extramilitary areas.

(k) The May law which can be invoked when—and preferably, as all leaders agree—only when existing civilian agencies responsible for the elimination of prostitutes in extramilitary areas fail to do so.

"Plain Words About Venereal Disease" tells of some plague spots—particularly in larger cities of the South and Southwest where segregated prostitution still prevails. The charge is made that 80 per cent of commanding officers are opposed to repression of prostitution and favor regulation (p. 109). Yet actual newspaper accounts from many areas show that many officers are taking their responsibility most seriously. Perhaps the nation as a whole is not too ready to cede more of its obligations to federal control.

ROENTGEN-RESISTANT VIRUS

The Shope papilloma virus is reported by Syverton¹ and his colleagues of the departments of bacteriology and radiology, University of Rochester School of Medicine, to be resistant to many thousand times the roentgen therapeutic dose necessary for cure of the cutaneous lesion that the virus produces in rabbits. Hornlike protuberances on the inner surfaces of the thighs, the back of the neck or other parts of the body are fairly common in wild rabbits; an occasional cottontail has the whole body covered with such "warts." The individual "horns" often reach a centimeter or more in diameter, with a height of 1.5 to 2 cm. In 1933 Shope,² of the Rockefeller Institute, reported that this cutaneous disease is readily transferred to wild rabbits by the application of glycerinated wart emulsions to slightly scarified cutaneous surfaces. The infective agent in such emulsions readily passes through the pores of a Berkefeld filter and exhibits other properties warranting its classification as an ultravirus. Rabbits with papillomas are partially or completely immune to reinfection, and their serums partially or completely neutralize the causative virus. Shope further found that, while the virus is readily transmissible in series in wild rabbits, it produces only nontransmissible first generation papillomas in domestic rabbits.

Interest in the Shope papilloma virus was heightened by the subsequent discovery³ that the nontransmissible warts in domestic rabbits often undergo progressive

malignant changes, many of them eventually giving rise to metastases in regional lymph nodes, lungs and other internal organs. This is of practical clinical interest, since analogous instances of graded alteration from papilloma to cancer are frequent in human pathologic conditions. These secondary cancers are readily transplanted into a new rabbit host. There is immunologic evidence of the continued presence of the Shope virus in these cancers.⁴

Nontransmissible papillomas of domestic rabbits react to roentgen rays as noninfectious tumors. Syverton and his colleagues,⁵ for example, found that a continuous or interrupted exposure of these papillomas to 2,000 roentgens will cure 16 per cent of the lesions and that 2,500 roentgens will cure 33 per cent, 3,000 roentgens 66 per cent and 3,500 roentgens or more 100 per cent of all experimental lesions. Parallel in vitro exposures of cell-free Shope virus showed no demonstrable reduction in dosage or virulence until the dose had been increased to more than 2 million roentgens. At least 6 to 7 million roentgens is required for full inactivation. The cell-free suspension of the papilloma virus thus requires several thousand times the therapeutic dose for its sterilization.

Evidently "the curative effect of x-ray on domestic rabbit papillomas (Shope) results from the direct action of the roentgen radiation on the rabbits' cells rather than on the virus." Whether or not the virus is actually killed by the mildly roentgenized rabbit cells has not yet been determined by the Rochester investigators.

Current Comment

PHARMACOPEIA TRUSTEES ASSURE DIABETIC PATIENTS SAFE INSULIN

The board of trustees of the United States Pharmacopeia, meeting in New York in a special session on November 23, gave special consideration to the problem presented by the expiration of patents on insulin, which occurs Dec. 24, 1941. Heretofore all insulin manufactured in the United States and distributed to persons with diabetes has been subjected to standardization and assay both by the American manufacturers and by the Insulin Committee of the University of Toronto, which holds the patents. The Board of Trustees recommended to the Committee on Revision of the United States Pharmacopeia that standards and assays for insulin be made available at the earliest possible moment, so that the Food and Drug Administration in the Federal Security Agency, which is charged by the Food, Drug and Cosmetic Act with enforcing these standards, may apply the standards immediately on expiration of the insulin patents. Because of the special nature of insulin it is proposed that the two assay control which now prevails under the insulin patents be continued and that the Food and Drug Administration shall not release any product

for general sale or distribution until it is assured that the product meets the standards and assays which the United States Pharmacopeia will specify. It is reported that already several foreign manufacturers have shipped insulin to the United States with a view to its distribution just as soon as the patents expire. Such insulin, and all other insulin, will be controlled by the action taken by the Board of Trustees of the Pharmacopeia, cooperating with the Food and Drug Administration. Meeting simultaneously with the Board of Trustees was a specially appointed group of experts from the United States and Canada who will develop the standards and assays to be included in the Pharmacopeia. Thus diabetic patients will be protected against the possibility of using inefficient or toxic products.

MALIGNANT LESIONS OF THE STOMACH

Adequate information on such surgical aspects of malignant lesions of the stomach as the risks involved in efforts to remove gastric carcinoma, on the effectiveness of gastrectomy when this can be successfully performed and on the percentage of the total number afflicted with carcinoma for whom extirpation is feasible seems heretofore to have been largely lacking. With special emphasis on these questions, Walters and his colleagues¹ recently reported in *THE JOURNAL* a review of all cases of malignant lesions of the stomach seen in the years 1907 to 1938 at the Mayo Clinic. Fifty-eight per cent of the 11,000 patients for whom diagnosis of malignant lesion of the stomach was made at the clinic during these years were subjected to surgical exploration. The average mortality rate was 16 per cent in cases of gastric resection for malignant disease. Thus the risk of this surgical procedure has been comparatively low and the mortality rate has decreased progressively in recent years. In 45 per cent of this group (i. e. 26 per cent of the original group) the lesion was removed. The five year survival rate after resection was 29 per cent, the ten year survival rate was 20 per cent and the fifteen year survival rate was 15.2 per cent. Of patients who did not have extension or metastasis, 44.7 per cent lived five years after leaving the hospital. After patients on whom resection has been performed have survived a five year period, the survival rate closely approximates that of the general population of similar age groups. Significantly, approximately one third of the patients who had carcinomatous lesions of the stomach which were resectable had symptoms of the so-called ulcer type of dyspepsia. In four fifths of these a temporarily effective response, with relief of pain, occurred when the patient was placed on a medical ulcer regimen. The Rochester investigators conclude from this review that the operation of partial gastrectomy affords an excellent means of treatment of cancer of the stomach, with successful cures in a large percentage of cases in which there are localized lesions regardless of the degree of malignancy. The authors further conclude that medical treatment of an ulcer type of dyspepsia should not be instituted without a roentgenologic examination to determine the exact location and nature of the lesion.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

MEDICINE AND SELECTIVE SERVICE

LEWIS B. HERSHEY

Brigadier General, U. S. Army; Director of the Selective Service System

Washington, D. C.

Everywhere I go I am under the necessity of thanking some one for a great deal, and it is true here. With 99 per cent of workers in Selective Service unpaid, it is necessary to be continually thanking some one. I do not possess control of the English language adequately to tell you what the work of anywhere from twenty thousand to fifty thousand of the medical profession of America—I am not counting the dentists—has done in the last year in Selective Service.

First I want to talk about the changes that are being made in the physical examination setup; second, I will mention rehabilitation; third, I want to thank you for what you are doing along these lines and beg you to keep on and perhaps to extend.

PHYSICAL EXAMINATION

The law says that the Army or the Navy shall be the final authority on the physical qualifications of the man. That has always been true. A year ago the Army did not feel quite as well organized as it does now to carry all of the responsibilities. Three years ago we planned a system not unlike the one we are going to attempt to use now. We had looked at the experience of a world war in which a quarter of a million people had been sent, many times, several hundred miles from home under the assumption that they were to be, in fact were, members of the armed forces of the United States, only to discover after a final physical examination in the camps that they did not possess the qualifications that the Army at that time insisted on. These men were dislocated from their businesses and from their homes. They were at some distance in time and in space thrown back to reallocate themselves. We realized that three years ago. But a year ago we were not able to get the Army to assume what we thought it should assume, namely to have the physical examination as near as possible to the place where the man lives and to have an examination that was—whether good, bad or indifferent—nevertheless final. After all, there is no perfection in this world. Perhaps there is no adequate physical examination; but we must agree that this is a physical examination and abide by the results of it.

In the World War the Army refused to permit the Selective Service System to say: This man has the qualifications for a soldier. I think it was the intent of the original Selective Service Law in 1917 that the determination was to be made at the local board as to whether or not the man did have the qualifications. If he did he was inducted and became from that time forth a soldier. But we have had the confusion over the years,

since the war, of the man who is discharged from the draft and the man who is discharged from the Army with some confusion as to the privileges that go with each.

We started out, however, with the dual examination. We tried to get the Army to bring its induction examination as near as we could in space to the place where the man lived, under the assumption that this at least would cut down the travel when he was rejected. We did not solve to suit us, or the public, the question of time. Many a man received his watch from the chamber of commerce, received the good wishes of his best girl, went to an induction station and found himself trying to get in rather quietly that night to his home town after having been rejected at the induction station. This was unfair to the man and unfair to the medical profession. Obviously the examining surgeon did his best and used his best judgment to try to determine whether that meat and bone and blood and hair added up to an individual who could be a soldier. Some other individuals of the same profession looked at it and said contrariwise. No one was wrong; both were right, but it was unfortunate that they disagreed.

We are trying to correct this situation. We are trying, if we can, to eliminate conflict between technical people, conflict that we understand but which the public does not understand. The public hangs on the words of the medical profession almost as it does on those of the priest. It believes the doctor more than it does the lawyer. When two doctors disagree it is unfortunate for the faith that the individual has in the profession. It is unfortunate for the profession that doctors are forced into a position where there may be some loss of faith. We hope the system we are going to start now will eliminate the time element and the conflict element.

THE SUPPLY OF PHYSICIANS

All that has been said during the past year on the necessity of deferment of doctors, of interns, of residents, of medical students and even of premedical students should make it unnecessary to speak about the need for physicians. If there is a scarcity of doctor hours in the United States there is no excuse for duplication of effort. Whenever there is a physical examination here that is absolutely going to be duplicated there it cannot be justified when each doctor hour is important. We have a right to try to have a physical examination that does not need to be duplicated either in paper work or otherwise. Many honest hours might be given to saving life that medical men have been obliged to spend in putting figures down somewhere that might be improperly interpreted and, even if prop-

early interpreted, would not lead to any action. Any time, any moment, any minute, any second we use in duplication is unwise. We are striving to try to make that which the medical examiner of the local board does complementary to what is being done later, rather than paralleling and duplicating.

THE SUPPLY OF MEN

We started with seventeen million five hundred thousand men, which seemed just lots and lots of men, but they have fallen out of the basket in one way or another. We do not have on hand as many as we should have with that large number. The fact that we are getting into somewhere near a shortage means that we must look over carefully the individuals we are rejecting.

I have no right to speak for the Army, but merely as one who has had some experience with it, and looking at it from the outside, I think it says "Here is an opportunity to have the healthiest Army any nation ever had." I think undoubtedly it has! I think it has a tendency to say "If there is any doubt about whether this man can pass or not, we will fail him." That is fine if there are enough men in the country to furnish the numbers wanted, but if the number is raised much from where it is now I fear we must depart from that. Hence we are tending to say to our medical examiners in this new method or modification of physical examination "You in the local board reject the man who is manifestly unfit for service. Where there is a question in your mind about whether he is unfit for service, record especially what you know about his emotional behavior patterns and forward it, and let the Army, which, after all, is by the act vested with the responsibility of deciding in what cases it wants to take the chance and in what cases it does not, from what it sees of the man and what it learns from what you have recorded, decide what it shall do with him."

CHANGE IN FORMS

We are trying to get a single form, which will be called 221, I think, that will be initiated by the local board and sent with the man to the examining station. We will have one complete record rather than too many incomplete records of form 200 here and form 221 there.

COMPENSATION FOR PHYSICIANS

There has been, perhaps because of misunderstanding and perhaps because of actual disagreement, much criticism of us, that we were trying to dump overboard ten or fifteen thousand doctors who had labored long and well. No such thing. I did feel and I do feel now that the doctors of America have put out, uncompensated, for Selective Service more than any other occupation. I do not believe we could expect to go on as we have in the last year, asking them to do this without compensation. I tell you frankly I don't want to try to operate Selective Service when we start on a pay basis, because the one thing that has kept us free from many undesirable things was the fact that we could get men who would work for nothing, who would not work for the wages the government could afford to pay. We have got something far beyond what you can hire at the wages we would expect to pay.

SERVICE OF PHYSICIAN ON DRAFT BOARDS

I would like to make the medical examiner of the local board something above some of the drudgery that has been imposed on him. I wish I could get the local boards to be able to have their medical examiner give

them more time in an advisory capacity. In this new change we look forward to a medical examiner as part of the board, not because he is going to do the examining, but because in hundreds of thousands of dependency cases, which involve 70 per cent of them, I find I have to have interpreted to me in a way I can understand a lot of the diseases of dependents. I should like to have these local boards have their medical examiner free enough so that he could say "That is what every 40 or 50 year old man has. Don't worry about that." Or say "He probably will die soon." But the words now supplied as reason for dependency might mean anything, from total disability to quite the contrary.

I would like to relieve the medical examiner as much as possible of the clerical work we have asked him to do. We have had some difficulty in interpreting what our form 200 means; I mention it with no criticism whatever. But these forms 200's are made in sixty-five hundred different places under at least ten thousand different circumstances. They go all the way from being made by kerosene oil and candle to the finest places one could have for examining. The individual examiners—some twenty thousand or more of them—look at life differently. When we try to equate what they have recorded on form 200 we doubt a little sometimes the validity because of the impossibility of supervising the environment under which the examinations have been made.

I believe that if form 221 is initiated in the local board and used to reject the man who is manifestly unfit, used to record everything known about the man who is either acceptable or at least on the borderline, these form 221's fabricated in a hundred places can be supervised to the place that they will tell a definite and believable story about the men who are examined.

Summarizing the examination, we want the manifestly unfit man rejected; we want the doubtful and the acceptable man forwarded. With rehabilitation coming on, we must put the Army on the spot with regard to the doubtful case to learn to what extent the man must be rehabilitated before the Army will accept him. Otherwise, if we commence to rehabilitate all of the individuals we think are rehabilitable we may have a difficult job trying to sell them to the Army.

REHABILITATION

The examiner of the future will, first, examine. Second, he will be recombining the registrants that have been rejected for individuals who, by reexamination, will prove they are fit for general service or who will be found to miss being fit for general service only by the degree that one can rehabilitate. He will be advising registrants as to what they should do to be rehabilitated, assisting many times as a community doctor in rehabilitating the individual and helping the local board and the state headquarters to exercise supervision in determining whether the man has been rehabilitated and in the, for us, rather difficult task of administering properly, efficiently and economically the fees connected with the rehabilitation. The advisory boards will, as they have in the past, tend to assist at times when the case seems a little beyond the capacity of the medical examiner.

The President decided that something must be done with regard to rehabilitation. Selective Service knew exactly who should do it—the Army. The Army wasn't so sure who should do it, but it knew exactly who shouldn't do it—the Army. At the end of the conference—I don't know whether it was because the Army

was a better salesman or what—we came away with a child we thought we had rather safely put in some one else's lap.

This question of rehabilitation is a large one; not only rehabilitation to the general service level or to the class B level but bringing men from the 20 to 40 per cent level, rehabilitating better citizens, without being soldiers, and rehabilitating members of the fair sex.

I am going to speak of rehabilitating individuals who are below the service level up to the service level. I shall not deal with rehabilitation up to the 1-B level. I shall not deal with rehabilitation from 20 to 40 per cent. The responsibility which the President put on us was attempting to push across the borderline the individuals who are hanging on the lower side of it. We feel that there are two or three hundred thousand individuals in that position.

We have asked the Army from now on, when it rejects a man, to say "Do you mean it or is he a person that could be brought up to the level if something was done to him?" Shortly we shall ask the local boards to go back over these lists and try to find for reexamination men who have had a high pulse or high blood pressure and perhaps nothing wrong with them except that they were frightened or even tried to be in that condition at the time they took the examination. We want the medical examiners to go back over these lists to find the individual who, by putting in a tooth or two, or something of that order, can be made a twelve-tooth soldier instead of a ten-tooth reject.

The first job is to take the individuals they are rejecting currently, second, to reexamine those who have some chance of becoming general service soldiers. These individuals will come back to the local board and, after consultation between the medical examiner of the local board and the man, will be given an opportunity, if he comes within the group we feel we can start with, to undertake rehabilitation at the expense, on a fee basis, of the United States in their local areas. Some of the individuals will accept it and some of them will not. We shall ask the Army to induct on a waiver those who do not. Otherwise, if there is no sting in the system I doubt seriously whether we shall accomplish much. If he accepts treatment, we visualize the individual being allowed to be doctored by the professional man he wants to choose. If he is too far away, we feel it is only fair to ask the registrant to pay his own way. We shall have to exercise some sort of control, especially over any physicians who may not do satisfactory work. We must have, after the job is done, approval by the local examiner or, if he needs help, by the medical advisory board, so that a selectee can be sent back to the Army for recheck and supposedly for induction. We must have help from the medical examiner and the medical examining board in taking care of the payment for these cases.

EDUCATION

You have been kind enough to listen to some of us at your national meeting. We do not want to be forward, but we would be glad to have that privilege continued. We hope next year in the summer, if it is reasonably cool and nice at Atlantic City, as I believe it will be, to bring an exhibit there. We understand that the American Medical Association, on occasion, speaks to a listening world of medical men. It might be that the time will come when we have words urgent enough that we might want you to say something in order to get them out, and get them out rapidly.

We shall be glad to give you information for the preparation of articles. We have no desire to send out canned information. We do want to be of assistance whenever we can remove doubt or misunderstanding.

We have had a very satisfactory arrangement during the past year. At your request we have sent people to participate in your state programs or, better still, you get our medical officer in your own state headquarters to take part. He knows more about the national picture than we do. He is no more confused, regardless of what you may think, and he knows a great deal more about what happens out in your state than we do. By and large, he ought to be a better man for you than any of us.

We do believe there might be, in the next two or three months, an excellent opportunity for joint meetings between the medical profession and the dentists in the several counties for consideration of the requirements of the Army and Navy. No one knows what day and hour the Navy may need some individuals by induction. We believe the question of rehabilitation, both medical and dental, will be something that most of these medical societies will be glad to know about.

FEES FOR REHABILITATION

I have two or three questions I shall raise. I should like to have any one give me the benefit of his information on what he thinks of the fees that the experience of the Veterans Bureau has developed for the treatment of different types of cases.

NEUROPSYCHIATRIC CASES

I should like to come on my knees, or any other way, to have the benefit of any one who may have experience on what to do about neuropsychiatric and alleged neuropsychiatric cases. I have had, for ten years and more, a definite interest in the peculiarities of human beings, especially as they keep an individual from being a good flier or a good driver of a tank or otherwise participating in modern war. No one has more sympathy than I have in the necessity for the Army to reject men who will not, under modern conditions, make soldiers, if we know what kind of individuals they are and if we know how to recognize them, and if we can instruct one hundred or two hundred men in that ability. It does not make much difference if one or two persons have that ability unless we can pass it on, because the decision has to be made in at least a hundred places. But I am frankly disturbed, and I have been brought to this point many times by talking with my medical examiners here and there over the country, when they say "I have known the boy since birth, and before, and I rather reject the idea that some one in Milwaukee or some other place in seven or eight minutes can find out things I have not been able to discover; with some knowledge of the human being and having made my living for forty years, or such a matter, practicing medicine, and thinking that, even though I am not an expert in that field, I rather reject the idea that some one can discover on such short notice that he possesses some of these disqualifying things."

I am frankly disturbed by the number of people turned down. I heard Dr. Abell speak this morning about the individuals who are not making the adjustment after they get to camp, and I am not surprised. Sometimes it does become a serious public relation when 40 per cent, as I know of in one place, of the people have been rejected because they presumably are

individuals who might become or were neuropsychiatric. If we get so that there are more than 51 per cent of that variety, I think the thing to do then is to have the kind of war that you can turn over to the majority, rather than expect the minority to wage it.

MEDICAL STUDENTS

The students are not by any right deferred. The law not only says they are not deferred but it says specifically that no class will be deferred. I think we have done very well by the medical student. We have done so well that sometimes I have actually been disturbed. But that is all right. I am perfectly willing, if for the greater good one must do the lesser evil. The local boards have been told that they may defer them, and "may" apparently was in capital letters because, by and large, they have. They have taken some who had been accepted for medical colleges and had not entered. I have the unfortunate task of trying to do something, after I get home, about a fellow who went to the wrong college. I don't know what the answer is going to be, but it isn't going to be right, whatever it is; I can assure you of that.

I am interested in protecting the medical profession, and I am perfectly willing to believe that all the things I have heard about the necessity for physicians are true. I am not so sure that we would do much better even if we had a law. We are faced continually, of course, not only with medical students but also with other students, chemists and a thousand other types of people.

I do believe you occupy a peculiar position in the minds of the people. I don't know whether you are going to kill the goose that lays the golden egg if you start the landslide on the other side. I don't know, but we shall continue regardless. The law would make

it easy for us. We could administer, we hope, easier than we could exercise judgment, but we have done much better than I expected. The only reason is that you have been pretty good salesmen. You still do have some of that combination that came from long ago when the medicine man was something a little more than a human being. May you continue to be.

I want to read a poem:

Ten little registrants standing in a line.
One joined the Navy, then there were nine.

Nine little registrants sitting on a gate.
One broke a vertebra, then there were eight.

Eight little registrants, talking 'bout heaven.
One went conscientious, then there were seven.

Seven little registrants, what a strange mix!
One became a pilot and then there were six.

Six little registrants very much alive.
One went and drowned and then there were five.

Five little registrants full of canny lore.
One stole a pig and then there were four.

Four little registrants, spry as they can be.
One became twenty-eight, then there were three.

Three little registrants, all alone and blue.
One fed his relatives, then there were two.

Two little registrants, what can be done!
One went to a psychiatrist, then there was one.

One little registrant classified 1-A.
Physically, mentally, morally okay.

One little registrant to tote a big gun.
He got married and then there were NONE!

ESTABLISHMENT OF DIVISION OF SOCIAL PROTECTION BY THE FEDERAL SECURITY AGENCY

According to a circular issued by the Adjutant General, October 2, the War Department has been advised by the Federal Security Agency of the recent establishment of a Division of Social Protection. The program of this new division follows. Copies of this program were sent by the Adjutant General's office to the commanding generals of all armies, army corps, corps areas and departments and the air force combat command, the chief of the armored force, the chief of the army air forces, the chief of staff, general headquarters and the commanding officers of exempted stations.

PROGRAM OF DIVISION OF SOCIAL PROTECTION

It is the purpose of the federal defense program to safeguard the health and morale of the armed forces and of the workers in defense industry. The Division of Social Protection has been formed to implement this purpose.

The first task of this division is to promote the public health by the reduction of venereal disease through the repression of commercialized prostitution.

The responsibility of the Division of Social Protection is by no means limited to this task, however.

The division is concerned with the protection of the community, and particularly of its girls and young women, from prostitution and other related social hazards. It also stimulates the constructive treatment and care of girls and women detained by the police.

In its long term aspects, this division is an integral part of the total public welfare program. It depends for its effective-

ness on the established agencies for public health, medical care, law enforcement, public assistance, recreation and child protection and in turn supplements these agencies in its particular field.

The program of the Division of Social Protection is summarized under four headings, relating to repression, treatment, protection and cooperation:

A. Repression of Commercialized Prostitution

1. The method adopted by the division toward the control of venereal disease is the repression of commercialized prostitution for the purpose of reducing to a minimum contacts by prostitutes with men in the armed forces and in defense industry.

2. While those interested in the program believe in its moral implications, the division considers it most important that the program be administered as a public health and protective measure without any suggestion of a moral crusade. One reason for this is the almost universal resistance of the citizenship of this country against governmental supervision of sexual morality. It may be that this resistance is allied to the fundamental American concept of religious liberty, since religion and morals are so closely associated. Just as the good citizen who is convinced of the importance of religion in human life may be strenuously opposed to any attempt by government to guide the practice of religion, so the good citizen while believing strongly that extramarital relations tend to destroy the values of family life may still be unwilling to see the federal government attempt to control such relations.

3. The program is unalterably opposed to any toleration of commercialized prostitution either in segregated districts or under medical supervision. This is based on experience and studies which have proved that segregation does not segregate

and that medical supervision alone cannot prevent the spread of venereal disease.

4. It is the policy of this division to work through state and local authorities. It is the hope of those responsible for the administration of this program that the repression of commercialized prostitution will continue as a permanent policy throughout this nation after this emergency is over. This can be accomplished only when state and local authorities and local communities are convinced that repression rather than toleration is the answer to the problem. It is therefore the responsibility of this division to attempt to bring about the voluntary adoption of its program by local authorities as a permanent policy. The establishment by military authorities of areas as out of bounds for men in uniform, or the invocation of the May act, are measures to be taken only as a last resort. Experience in the last war, and the attitude of federal and local authorities to date in this emergency, all point to the likelihood that our program can be established in most defense areas on a voluntary basis.

B. Treatment of Prostitutes

1. The aim of this program is to get local authorities to deal with the individual prostitute as a human being with the aim that those who are capable of rehabilitation can be helped back to ways of life which are more constructive.

2. Our field representatives will seek the establishment of facilities for the classification of girls and women picked up by the police so that those who can be helped can be separated from those who show little hope of rehabilitation, and so that those in need of special treatment can be given such treatment or sent to places where treatment is available.

3. Our field staff will seek provision of adequate facilities when needed for the treatment of women, on an individualized basis, whether that treatment is (a) medical, (b) custodial, (c) training, (d) placement in jobs, (e) placement in family foster homes, (f) assistance to return to their own homes or (g) other constructive measures.

C. The Protection of Girls in Defense Areas

1. Protection of girls in defense areas involves supervision of places of employment where (a) wages may be inadequate to meet the girls' minimum requirements for food and shelter and (b) where the girl employee may be subject to pressure to engage in prostitution as a consequence of her employment.

2. It likewise involves supervision of places of commercial recreation where girls may be in danger of being led into prostitution.

D. Cooperation with other Agencies

Those engaged in this program are well aware that this division is only one of many agencies whose work is necessary to bring about the desired results.

1. We do not attempt to work with the man in uniform, leaving his education with reference to social hygiene and the control of his actions to the military and naval authorities.

2. We are fully convinced of the importance of such positive action as the provision for recreation and other leisure time activities for the soldier and sailor but leave that to the military and naval authorities as supplemented by the Division of Recreation of this agency, by the USO and by many other interested agencies and organizations.

3. We are vitally concerned that persons with venereal disease receive prompt, effective and conclusive treatment so that they may first be made noninfectious and, second, cured, and we know that the U. S. Public Health Service is on that job.

4. In the field of law enforcement we depend on local authorities, the Military Police and, in the exceptional case, on the Department of Justice.

5. In the care of the apprehended prostitute and in the protection of girls and young women in danger of prostitution, we depend on the facilities and resources of the agencies of local, state and federal governments.

Conclusion

The Division of Social Protection, then, takes its place as an integral part of the Office of Defense Health and Welfare Services. On the state and local level it will maintain its responsibilities in a cooperative and constructive fashion, working with public officials, private agencies and interested citizens. It stands ready to modify its efforts and plans in accordance with new experiences and developing community needs. It is the will and desire of the American people to protect the health and morale of the men in its armed forces and defense industries. The Division of Social Protection will contribute to this end. We intend so to plan and execute the program that it will be accepted by the states and become the permanent policy of local government throughout this nation.

ELIOT NESS.

Director, Division of Social Protection.

GOVERNMENT STILL NEEDS PHYSICAL THERAPY AIDES

The U. S. Civil Service Commission is intensifying its recruiting efforts to secure physical therapy aides for the government service. About one hundred appointments were made in the last year, and it is expected that more than three hundred and fifty appointments will be made next year in the War Department and Veterans Administration. Positions are open ranging from the student grade to the full grade. Applications may be filed at any time at the commission's central office in Washington, D. C.

A new examination announcement—No. 24-revised—for physical therapy aide (\$1,800 a year) and junior grade positions (\$1,620 a year) has been issued which cancels and supersedes the announcement No. 24 issued January 20. The education and experience requirements remain substantially the same, but, in order to build up a reservoir of qualified people, applications will be accepted for these two positions from persons who do not meet the regular physical and age requirements. Such eligibles cannot receive regular probational appointment but may be considered for filling national defense needs. Applicants for probational appointment must not have passed their forty-fifth birthday. Persons who received eligible ratings under the examination announced in January need not file new applications unless they have acquired sufficient additional experience to warrant consideration for a grade higher than the one in which they were originally rated.

The examination announcements for physical therapy aide and the junior grade (announcement No. 24-revised) and for student and apprentice physical therapy aide (announcement No. 117 issued July 31) may be consulted or obtained at any

first or second class post office or at the Civil Commission, Washington, D. C. Persons who are interested in and qualified for physical therapy work are urged to file their applications at once.

ARMY HEALTH RATES ARE BETTER TODAY

The death rate in the Army from disease now is less than one-tenth what it was in the World War years of 1917-1918, and the venereal disease rate is less than half what it was in that period, the Surgeon General of the Army reported to the War Department on November 14. In 1917 the annual rate for all venereal diseases was 107 per thousand soldiers. In 1918 it was 90 per thousand. The present annual rate approximates 40 per thousand soldiers. The annual rate for syphilis in the Army has showed a consistent decline. In 1918, for instance, the rate was 17.56 per thousand. Progressively the rate dropped to 6.59 in 1939, 5.7 in 1940, and in August of this year it was 5.5. The August annual rate per thousand soldiers for all venereal disease was 43. Incidentally, Selective Service examination of prospective trainees showed that 45.2 men of every thousand were infected with syphilis.

The reductions not only in the death rates from disease but also the rates of venereal disease have resulted from an unrelenting campaign by the Army. Newer, more effective medical discoveries and methods have aided considerably. The campaign against venereal disease has brought intensified education in hygiene in the Army, which has recognized that the cooperation of civil authorities in the suppression of prostitution is essential to the suppression of venereal disease in the armed forces.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

WAR DEPARTMENT

The following additional medical reserve officers have been ordered to extended active duty by the War Department, Washington, D. C.:

BORKON, Maurice, 1st Lieut, West Kalispell, Mont
COCKE, John Alexander, 1st Lieut, Charlottesville Va
COLDWATER, Kenneth Bryson, 1st Lieut, St Louis
MEAGHER, George Beyer, 1st Lieut Depue, Ill
MENDEL, Walter H, Captain, Haverstraw, N Y
TRIPODI, Anthony, Lieut Colonel, St Louis

Orders Revoked

AHERN, Eugene E, 1st Lieut, Minneapolis
AUSTER, Benjamin, 1st Lieut, New York
CRAIG, Paul C, Captain Reading, Pa

DeWIRE Merrill B, Major, Reading, Pa.
DIAMOND, Bernard L, 1st Lieut, Ann Arbor, Mich
DINGMAN, Reed Othelbert, 1st Lieut, Ann Arbor, Mich
FAWCETT, Robert M, 1st Lieut, Pittsburgh.
FLANN, Vincent P, Captain, Pasadena, Calif.
HALE Clayton H, 1st Lieut, Manlius, N Y.
HANSEL, Robert J, Captain, Orlando, Fla
HOBART, Francis W, Captain, Lake City, Iowa
JARRETT, John T, 1st Lieut, Richmond, Va
KLINE, Edward M, Captain, Cleveland
LAUGHLIN, Victor C, Major, Cleveland
OVERTON, Lewis M, Captain, Des Moines, Iowa
RUDI, Herbert J, Captain, St Louis
TASCARELLA, James W, 1st Lieut, Brooklyn
WATNER, Amos S, 1st Lieut, Philadelphia

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fourth Corps Area, which comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

GARDINE William G Captain, Oteen, N C, Camp Gordon Ga
CORPENING, Albert Edward, 1st Lieut, Tampa, Fla, Camp Forrest, Tenn
METTETAL, Ray W, 1st Lieut, Johnson City, Tenn, Camp Gordon, Ga
REECE John Cochrane 1st Lieut Newton, N. C Fort Bragg, N. C
WINTERS, Allen C, Captain, Alexandria, La, Camp Gordon, Ga.

Orders Revoked

CARITHERS, Hugh A, Jr, 1st Lieut, Winder, Ga
CROOM, Arthur B 1st Lieut, Maxton, N C
GARRETT, Brook C, Captain, Shreveport, La
GESSLER, Carl N, 1st Lieut, McMinnville, Tenn
HAWES, James B, 1st Lieut, Greenville, N C
HUDSON, Harry Horatio 1st Lieut, Cleveland Tenn
HUNTER, William Blair, Major, Lillington, N C
PARNELL, Homer S, Jr, 1st Lieut, New Orleans
PITT, Charles K, 1st Lieut, Trinity, Ala
SAFELY, Thomas J, Jr, 1st Lieut, Drew, Miss
THOMAS, Ford Alton, Captain, Urania La
WILLIS, Charles A, 1st Lieut, Bambridge, Ga

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Michigan and Illinois:

ADLAND, Abe, Captain, Sioux Falls, S D, Reception Center, Scott Field, Ill
BULLOCK, Norman Charles, 1st Lieut, Rockford Ill, 1608th Corps Area Service Unit, Camp Grant Ill
CENEDELLA, Francis J, 1st Lieut, Moline, Ill, U S Army Induction Board, Peoria, Ill
FITZGIBBONS, James P, 1st Lieut, Chicago, Reception Center, Camp Grant, Ill
GRIEP, Ernst August 1st Lieut, Quincy, Ill, 64th Medical Regiment, Camp Bowie, Texas
GRIFFITH, Paul R, 1st Lieut Berwyn, Ill, 33d Division, Camp Forrest, Tenn.

HAUGE, Howard Leroy, 1st Lieut, Blanchardville, Wis, 23d Evacuation Hospital, Fort Custer, Mich
ISOE I M, 1st Lieut Chicago, U S Army Air Base, Tucson, Ariz
JACK Nelson Briggs, 1st Lieut, Decatur, Ill, Headquarters and Station Complement Camp Shelby Miss
LEES, William Morris, 1st Lieut, Chicago, U S Army Induction Station, Kalamazoo, Mich
MOORE, Rollin Samuel, 1st Lieut, Streator, Ill, U S Army Induction Board, Peoria, Ill
RITTER, Jerome, 1st Lieut, Danville, Ill, U S Army Induction Station, Kalamazoo, Mich
RESTIVO, Jack Liborio, 1st Lieut, Chicago, Richey Flying Service, Vernon, Texas
RUBINFELD, Samuel H, 1st Lieut, Ontonagon, Mich, Coleman Flying School, Ltd, Coleman, Texas
STOBBE, Godfrey Dorr, 1st Lieut, Detroit, Station Hospital, Savanna Ordnance Depot
WOLTERS, Simon Lloyd, 1st Lieut, Chicago, 1607th Corps Area Service Unit, Fort Sheridan, Ill

Orders Revoked

BARBER, Kent W 1st Lieut, Quincy, Ill
BERARDI, James B 1st Lieut, Dwight, Ill
BERGSTROM, Paul L, 1st Lieut, Kirkland, Ill
BICA, Getano A, 1st Lieut, Chicago 5th Infantry Division, Fort Custer, Mich
BLUEFARB Samuel M, 1st Lieut, Chicago
BORKON, Eli L, 1st Lieut, Carbondale Ill, Headquarters and Station Complement, Corps Area Service Command, Camp Davis, N C
BOWERS, Paul A, 1st Lieut, Chicago
BRAND Ashley M, 1st Lieut, Chicago
BROWN, Wilbert O, 1st Lieut, Chicago
CHABNER Louis, 1st Lieut, Shelbyville Ill
COHLER, Bernard E, 1st Lieut, Chicago
CONGER, April B 1st Lieut, Ann Arbor Mich
COVELL Kermit W 1st Lieut, Racine Wis
CUTRERA Hugo T, 1st Lieut, Chicago Army Air Base, Tucson, Ariz.
DEL BECCARO, Edward V, Major, Chicago
DICKERSON, Donald L, 1st Lieut, Danville, Ill
EMANUELE Nicola V, 1st Lieut Chicago
FLEMING, James F, 1st Lieut Chicago
FORTNER, Roscoe J, Captain, Three Rivers, Mich
GALL John H, Lieut Colonel Chicago
GUNDERSON, Robert H, 1st Lieut, Beloit Wis

HARLEY, Garth H, 1st Lieut Detroit
HERZOG, Paul S, 1st Lieut, Kenosha Wis
MARCHMONT ROBINSON, Harry, 1st Lieut, Chicago
O'BRIEN, Donald Erwin, 1st Lieut, Chicago, 1627th Corps Area Service Unit, Scott Field, Ill
LYNN, Harold Phillip, 1st Lieut, Ypsilanti, Mich, Headquarters and Complement, Camp Shelby, Miss
O'NEILL, Paul J, 1st Lieut, Alton, Ill, Corps Area Laboratory, Fort Sheridan, Ill.
PERKINS, Robert D, 1st Lieut, Moline, Ill
PORTS, Preston Wesley, Captain, Farmington, Mich, Station Complement, Selfridge Field, Mich
PRZYGOCKI, Stanley F, Captain, Chicago
ROKITA, Adam W, 1st Lieut, Barry, Ill
ROSENBERGER, Maurice D, 1st Lieut, Oak Park, Ill, 1605th Corps Area Service Unit, Fort Custer, Mich
SIBRANS, William Albert, 1st Lieut, East Detroit, Mich, Will Rogers Field, Oklahoma City
SLIVE Alexander, 1st Lieut, Chicago
SPRINGER, Eugene W, 1st Lieut, Iowa City
WINSAUER, Henry John, 1st Lieut, Kohler, Wis, Headquarters and Station Complement, Camp Shelby, Miss

ORDERED TO FOREIGN DUTY

CHAIHAN Alexander Robert, 1st Lieut, Medical Detachment, U S Troops Seward Alaska
DENEFF, Carl, 1st Lieut Hickam Field Hawaii
DISON, John Milnes 1st Lieut, Station Hospital Borinquen Field Puerto Rico

EMMERLING, John Frederick, Captain, Tripler General Hospital, Honolulu Hawaii
GILSDORI, Amos Roy, 1st Lieut, Station Hospital, Fort Richard on, Alaska

ORGANIZATION SECTION

OFFICIAL NOTES

THE ATLANTIC CITY SESSION

Section Representatives to Scientific Exhibit

Representatives to the Scientific Exhibit have been appointed from the different sections of the Scientific Assembly as follows

- Practice of Medicine—Louis B. LaPlace, 1900 Rittenhouse Square, Philadelphia
Surgery, General and Abdominal—Grover C. Penberthy, 1553 Woodward Avenue, Detroit
Obstetrics and Gynecology—Charles Edwin Galloway, 636 Church Street, Evanston, Ill.
Ophthalmology—Georgina Dorak Theobald, 120 Medical Arts Building, Oak Park, Ill.
Laryngology, Otolaryngology and Rhinology—Fred W. Dixon, 2060 East Ninth Street, Cleveland
Pediatrics—Arthur F. Abt, 104 South Michigan Avenue, Chicago
Experimental Medicine and Therapeutics—Dwight L. Wilbur, 490 Post Street, San Francisco
Pathology and Physiology—F. W. Konzelmann, Temple University Hospital, Philadelphia
Nervous and Mental Diseases—F. P. Moersch, 102 Second Avenue S. W., Rochester, Minn.
Dermatology and Syphilology—Hamilton Montgomery, 102 Second Avenue S. W., Rochester, Minn.
Preventive and Industrial Medicine and Public Health—Paul A. Davis, Akron, Ohio
Urology—John H. Morrissey, 40 East Sixty First Street, New York
Orthopedic Surgery—Jesse T. Nicholson, 1614 Locust Street, Philadelphia
Gastroenterology and Proctology—Grant H. Laing, 122 South Michigan Avenue, Chicago
Radiology—S. W. Donaldson, 326 North Ingalls Street, Ann Arbor, Mich.
Anesthesiology—Paul M. Wood, 745 Fifth Avenue, New York

Application blanks for space in the Scientific Exhibit at the Atlantic City session may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD IN CHICAGO, NOV. 13 AND 14, 1941

A full day meeting of the Board of Trustees was held on Thursday, November 13, which was preceded by a full day meeting of the Executive Committee. The Board met again on Friday morning, November 14, to complete its deliberations and then adjourned to attend the Annual Conference of Secretaries of Constituent State Medical Associations.

WOMAN'S AUXILIARY

Wisconsin

The Rock County auxiliary cooperated with the Beloit Y. M. C. A. and seventeen other city, state and national organizations in presenting a "Hall of Health" exhibit patterned after those at the San Francisco and New York world fairs. The American Medical Association and the Wisconsin Women's Field Army for the Control of Cancer lent exhibits. A theater with movies, slides and plays including the highly praised film "Good-Bye Mr. Germ" was an outstanding feature. Among other cooperating organizations were Beloit College, the state board of health, the Wisconsin Anti-Tuberculosis Association, the American Museum of Health, the state medical association, the Beloit membership of the American Dental Association and many civic organizations.

The auxiliary to the Dane County Medical Society met at Cambridge and voted to appropriate \$50 to place Hygeia in

BINDING OF JOURNAL IN THREE VOLUMES A YEAR

Because of the growth of *THE JOURNAL* and the weight of the present volumes, it was decided to bind *THE JOURNAL* in three, instead of in two, volumes each year beginning with 1942.

DR. T. G. KLUMPP ELECTED TO MEMBERSHIP ON COUNCIL ON PHARMACY AND CHEMISTRY

Dr. T. G. Klumpp, Secretary to the Council on Pharmacy and Chemistry, was elected to membership on the Council.

REVISION OF STANDARDS FOR CLINICAL THERMOMETERS

The Board approved a revision of the standards for clinical thermometers established by the Division of Trade Standards, National Bureau of Standards, U. S. Department of Commerce, and reaffirmed the policy of the Association not knowingly to accept advertising for any product that does not comply with the standards of that bureau.

DR. WALTER E. VEST SUCCEEDS DR. E. J. GOODWIN ON COMMITTEE OF COOPERATIVE MEDICAL ADVERTISING BUREAU

Dr. Walter E. Vest, editor of the *West Virginia Medical Journal*, was elected to succeed Dr. E. J. Goodwin on the Committee of Cooperative Medical Advertising Bureau.

ASSOCIATION'S BROADCAST "DOCTORS AT WORK"

The Board approved plans for the continuation of the broadcasting program "Doctors at Work." These programs will be broadcast on Saturdays from 5:30 to 6 p. m., eastern standard time, on the Red network, beginning December 6, and will run approximately twenty-six weeks.

REPRESENTATIVE TO NATIONAL HEALTH COUNCIL

Dr. W. W. Bauer was designated to represent the American Medical Association on the Committee for the Study of Voluntary Health Agencies, which is being established by the National Health Council.

MISCELLANEOUS

Careful consideration was given by the Board to the financial reports for the current year, to plans covering certain phases of the Pan American Session of the Association to be held in 1942, to plans for the celebration of the Centennial of the Association in 1947, to resolutions and memorials referred to it by the House of Delegates at the last annual session and to numerous other subjects, some of which will be reported on at a later date.

schools chosen by the committee and also to donate \$20 to the loan closet to purchase needed articles. At a recent meeting held at the home of Mrs. N. A. Hill in Madison, thirty-eight members were present. The Hygeia chairman reported that four towns had accepted the offer to place Hygeia in their town libraries. Also the county nurses have assigned forty-eight schools in the county to receive the publication. It was reported that twenty lavettes had been purchased for use by the loan closet.

At the meeting of the auxiliary to the Waukesha County Medical Society recently in Waukesha, Dr. Irene Stumper of Oconomowoc spoke on "Women in Medicine."

In May, a President's Tea at the home of Mrs. H. G. Nixon Hartland, was held. George B. Larson, assistant secretary of the state medical society, gave an address on voluntary sickness insurance.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Change in Health Officers.—Dr. John I. Mitchell, Haleyville, has been appointed health officer of Winston County, succeeding Dr. William A. Dodson Jr., Double Springs, who resigned to accept a position with the U. S. Public Health Service.

Society News.—The Northwestern division of the Medical Association of Alabama was addressed at Berry, October 21, by Drs. M. Vann Adams, Mobile, on "Treatment of Cerebral Complications in the Newborn"; John M. Townsend, Birmingham, "Surgical Management of the Ruptured Bladder and Urethra"; William D. Anderson, Tuscaloosa, "Indications for X-Ray Therapy in Everyday Practice"; Lee F. Turlington, Birmingham, "Endometriosis," and Edgar G. Givhan Jr., Birmingham, "Migraine."

CALIFORNIA

Officers of State Board.—Dr. Clark L. Abbott, Oakland, was recently elected president of the state board of medical examiners at a meeting in Sacramento and Dr. Fred R. DeLappe, Modesto, was named vice president to succeed Dr. George Thomason, Los Angeles. Dr. Charles B. Pinkham, San Francisco, was reelected secretary of the board for the twenty-eighth consecutive year.

Society News.—A panel discussion on "Trauma to the Hand" constituted the program of the Los Angeles Surgical Society at its meeting on November 14. The speakers were Drs. William S. Kiskadden, Joseph H. Boyes, Paul E. McMaster and Frank J. Breslin. All are from Los Angeles. —Dr. Axel N. Arneson, St. Louis, addressed a joint meeting of the radiologic section and the Los Angeles County Medical Association, November 6, on "Carcinoma of the Corpus Uteri." —Charles-Edward A. Winslow, Dr.P.H., Anna M. R. Lauder professor of public health, Yale University School of Medicine, New Haven, discussed "Health Problems of Defense" before the San Francisco County Medical Society on November 11. Dr. Winslow is now serving as Rosenberg lecturer in the public social services at the University of California, Berkeley.

Course of Instruction on the Cyclotron and Its Products.—The department of medicine of the University of California Medical School, San Francisco, announces an open course on the cyclotron and its products. The instructors are members of the staff of the University of California Radiation Laboratory in Berkeley. The course is given in recognition of the fact that the use of the cyclotron and its products has proved their worth and that they are ready for use in biology and medicine. The cyclotron was invented by Ernest O. Lawrence, Ph.D., professor of physics at the University of California, Berkeley, and head of the laboratory, and 1939 Nobel Prize winner, and development of the apparatus in medical and biologic research has been under the direction of Dr. John H. Lawrence, assistant professor of medicine at the medical school. The 225 ton "atom smasher" at the University of California is called the "medical cyclotron."

DELAWARE

State Medical Election.—Dr. William Marshall Jr., Milford, was elected president of the Medical Society of Delaware at its annual meeting in Wilmington, October 7. Other officers include Drs. Richard C. Beebe, Lewes, and Paul R. Smith, Wilmington, vice presidents; Alfred Leon Heck, Wilmington, treasurer, and Charles L. Munson, Wilmington, secretary. Dover was selected as the place for the 1942 session.

DISTRICT OF COLUMBIA

Davidson Lecturer Announced.—Dr. Robert J. Coffey, professor of experimental surgery, Georgetown University School of Medicine, Washington, delivered the Davidson Lecture for 1941 before the Medical Society of the District of Columbia on October 8. The Davidson lecturer is chosen on alternate years by a special committee, the selection going to the winner of an essay competition. Dr. Coffey's paper was entitled "Recent Advances in Diseases of the Pancreas." Dr. Coffey graduated at Georgetown in 1932. The Davidson Lecture was established in 1929.

ILLINOIS

Joint Session of Societies.—The sixty-seventh annual meeting of the District Medical Society of Central Illinois was held jointly with the Sangamon County Medical Society in Springfield on November 6. Speakers included:

Dr. Frederick F. Boyce, New Orleans, Basic Problems of Acute Appendicitis and Cancer of the Stomach.
Dr. Kenneth H. Schnepf, Springfield, Diaphragmatic Hernia.
Howard J. Shaughnessy, Ph.D., Chicago, Encephalitis of Virus Origin.
Dr. Burle B. Madison, Springfield, Nonspecific Infections of the Urinary Tract.
Dr. Fred M. Smith, Iowa City, Certain Aspects of the Treatment of Cardiac Failure.

Clinical Meeting of College of Physicians.—An annual roundup of all fellows and associates of the American College of Physicians of Illinois will form an all day meeting at the New Wesley Memorial Hospital, Chicago, on December 6. The program will include short papers and a clinical pathologic conference. In the evening brief addresses will be delivered by guests. The principal speaker of the evening will be Dr. Edward L. Bortz, associate professor of medicine, the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, Philadelphia, on "Medical Progress and the American College of Physicians."

Chicago

Annual Dinner of Institute of Medicine.—The twenty-sixth annual dinner and meeting of the Institute of Medicine of Chicago will be held in the Boulevard Room of the Stevens Hotel, December 2. Dr. Rollin T. Woodyatt will deliver the presidential address on "The Story of Acidosis."

Lecture on Beaumont.—Dr. Arno B. Luckhardt, professor of physiology, University of Chicago School of Medicine, will lecture under the auspices of the Robert Sonnenschein Study Group for Medical History at the Michael Reese Hospital, December 10, on "Dr. William Beaumont and the Medical Epic of the Northwest Territory."

Branch Meetings.—The North Shore Branch of the Chicago Medical Society will be addressed, December 2, by Drs. Howard A. Lindberg on "Up to Date Treatment of Pneumonia" and Edwin M. Miller, "Surgical Emergencies of the Newborn." —The North Side Branch was addressed, November 6, by Drs. Henry H. Turner, Oklahoma City, on "Fatigue States in Endocrine Disorders," and Elmer L. Sevringhaus, Madison, Wis., "Menopause and Hypofunction of the Ovaries."

New Cancer Committee.—The Chicago Cancer Committee, Inc., has been organized as a liaison educational agency; Dr. Ludvig Hektoen, executive director of the National Advisory Cancer Council, is chairman. The purpose is to disseminate information on the symptoms, diagnosis, treatment and prevention of cancer, to aid indigent cancer patients to obtain treatment and to work toward the establishment of hospital and other necessary facilities. Dr. William F. Petersen, chairman of the board of governors of the Institute of Medicine of Chicago, is treasurer of the committee; the directors include Dr. John A. Wolfer, chairman of the cancer committee of the Illinois State Medical Society; Dr. Bowman C. Crowell, associate director of the American College of Surgeons; Mrs. Arthur I. Edison, state commander of the Women's Field Army of the American Society for the Control of Cancer, and Mr. Alexander Ropchan, director, health division, Council of Social Agencies, secretary.

IOWA

Society News.—Dr. Louis J. Karnosh, Cleveland, will discuss "Psychiatric Problems in General Practice" before the Linn County Medical Society, December 11, in Cedar Rapids. Dr. Arlie R. Barnes, Rochester, Minn., conducted a clinic on cardiac cases before the society November 13. —Dr. Rolland Russell Best, Omaha, discussed "Causes of Continued Disability Following Cholecystectomy: Management" before the Chickasaw County Medical Society in New Hampton, November 5. —Dr. Lloyd H. Mousel, Rochester, Minn., addressed a recent meeting of the Cerro Gordo County Medical Society in Mason City on "Recent Developments in Anesthesia."

New Members of Fifty Year Club.—Dr. Ferdinand J. E. Smith, Milford, was presented with a plaque by the state medical society in recognition of his completion of fifty years in the practice of medicine. Certificates of membership in the "Fifty Year Club" of the state medical society were awarded to the following members of the Polk County Medical Society in October: Drs. Andros Carson, Des Moines; Jared D. Kerlin, Des Moines; Ellis G. Linn, Des Moines; David T. Nicoll, Mitchellville; Christian Nysewander, Des Moines, and Fred L. Wells, Des Moines.

MARYLAND

Society News.—The Baltimore City Medical Society and the Medical Society of the District of Columbia held a joint meeting in Baltimore, November 7; the speakers were Drs. Hugh H. Hussey Jr. and James Ross Veal on "Treatment of Thrombophlebitis"; Worth B. Daniels, "Epidemic of Bronchopneumonia of Unknown Etiology," and Clarence K. Fraser and John L. Parks, "Lesions of the Vulva." All were from Washington.

Dr. Howard Kelly's Library.—The Howard A. Kelly Library, said to be one of the largest private collections in the country, is being sold in separate items, newspapers reported, November 4. In explaining the reason for the disposal, Dr. Kelly, professor emeritus of gynecology, Johns Hopkins University School of Medicine, Baltimore, is reported to have said "I want to be sure that my books will get into good hands." Dr. Kelly has given collections to various units of Johns Hopkins University, including a group dealing with the life and times of Florence Nightingale to the school of nursing and one on geology and Africa to the Homewood Library of the university. He also gave an extensive mycologic collection known as the Louis C. C. Krieger Mycological Library to the University of Michigan, Ann Arbor. Dr. Kelly began his book collection in 1885.

MICHIGAN

First Award of Foster Welfare Foundation Prizes.—The first award of the prizes for papers on medical research by the Foster Welfare Foundation of Grand Rapids were made at a dinner, October 28. Drs. John T. Hodgen and Charles H. Frantz are winners of the \$100 prize offered for Blodgett Memorial Hospital for their paper on "Juvenile Kyphosis." This paper also won the grand prize of \$100. Dr. Henry P. Kooistra is winner of the prize for the staff of St. Mary's Hospital for his work on "Pilonidal Sinus—Review of the Literature and Report of 350 Cases." The three winners this year are all graduates of the University of Michigan Medical School, Ann Arbor. The creation of these awards was announced last year. They are available to the staffs of the Blodgett Memorial Hospital, St. Mary's Hospital and Butterworth Hospital, all of Grand Rapids, under the Foster Welfare Foundation of Grand Rapids, founded under the will of the late Clara J. Foster of Newaygo. The conditions stipulated that three \$100 cash prizes will be awarded, one for each of the hospitals named, to the author or authors of the best medical paper written by a member of the staff of the hospital, provided the staff of such hospital produces at least five medical papers, including the winning paper, which have been accepted for publication by either a national or a state medical journal during the year commencing May 1, 1940 and ending May 1, 1941. The Kent County Medical Society named the committee of three to judge the papers, representing each hospital, and Charles Judson Herrick, Sc.D., Grand Rapids, professor emeritus of neurology, University of Chicago School of Medicine, Chicago, cooperated with the faculty of the University of Michigan Medical School in judgment of the papers.

MISSOURI

Dr. Koch Lectures in St. Louis.—Fred C. Koch, Ph.D., formerly Frank P. Hixon distinguished service professor and chairman of the department of biochemistry, University of Chicago, Chicago, lectured at the St. Louis University School of Medicine, St. Louis, October 24, on "Recent Biochemical Studies on Androgens."

Society News.—Bradley M. Patten, Ph.D., Ann Arbor, discussed "Development of the Cardiovascular System with Micro-Moving Pictures of Living Embryos" before the Kansas City Academy of Medicine November 21.—Dr. Lawrence D. Thompson, St. Louis, presented a review of the incidence and therapy of pneumococcal pneumonia before the St. Louis County Medical Society on October 8 in St. Louis.

NEW JERSEY

Public Health Meeting.—The New Jersey Health and Sanitary Association will hold its sixty-seventh annual meeting at the Stacy-Trent Hotel, Trenton, December 5. Dr. John L. Rice, health commissioner of New York City, will deliver the principal address, on "Changing Trends in Public Health."

Annual Fall Clinical Conference.—The Medical Society of New Jersey will hold its fourth annual fall clinical conference in Elizabeth, December 3. The morning will be given over to special sessions in various industrial plants. At Elizabeth General Hospital there will be during the entire morning a presen-

tation of cases from the department of malignant and allied diseases and discussion of diagnosis and treatment. The afternoon will be devoted to papers sponsored by the sections of the society:

Dr. Henry C. Barkhorn, Newark, Tonsillectomy by Eversion and Snare.
Dr. Hyman I. Goldstein, Camden, Ulcer and Cancer of the Stomach, Through the Ages.
Dr. Edward C. Klein Jr., Newark, Circulation Time and Venous Pressure: Procedure for the General Practitioner.
Dr. Robert A. MacKenzie, Asbury Park, Ovarian Tumors Complicating Pregnancy.
Dr. Albert S. Harden Jr., Maplewood, Breast Feeding, Its Uses, Production and Preservation.
Dr. Harry J. Perlberg, Jersey City, Radiology in Obstetrics.
Dr. Elmer P. Weigel, Plainfield, Compound Fractures.

Dr. Edward G. Bourns, Westfield, will be the toastmaster at the dinner in the evening, and Johannes Steel, radio commentator, will discuss "World Conditions: A Realistic Appraisal."

NEW YORK

Symposium on Cancer.—The Nassau County Cancer Committee sponsored a symposium on gastric cancer before the Nassau County Medical Society in Garden City, October 28. The speakers were Drs. Fred W. Stewart, New York, pathology; Robert P. Ball, New York, x-ray diagnosis, and Ashley W. Oughterson, New Haven, Conn., surgery.

Society News.—Dr. Henry van Zile Hyde, New York, medical officer, second defense area, addressed the Onondaga County Medical Society, Syracuse, October 7, on "The Health Defense Program," and Dr. Edgar M. Neptune, Syracuse, presented a motion picture on "Treatment of Hip Fractures."

—Dr. Bertram S. Levinson, Syracuse, presented a paper before the Syracuse Academy of Medicine, October 21, on "Laboratory and Clinical Observation on 100 Ambulatory Cases of Hypertension" and Drs. Joseph Ernest Del Monico and Charles C. Heck, Syracuse, presented a motion picture on "Fracture of the Patella: Treatment by Excision."—Dr. Leon H. Griggs, Syracuse, addressed the quarterly meeting of the Ontario County Medical Society, Canandaigua, October 14, on "Diseases of the Skin."—Dr. Felix Ottaviano, Oneida, discussed "The Paraffin Pack in the Treatment of Pulmonary Tuberculosis" before the Oneida Medical Society, Oneida, recently.

New York City

Doctors Orchestra Starts Rehearsals.—The Doctors Orchestral Society has resumed its weekly rehearsals at the National Hospital for Speech Disorders under the direction of Mr. Fritz Mahler as conductor. The annual concert will be given at Town Hall on May 8, 1942.

Dr. McGregor to Retire from Teaching.—James H. McGregor, Ph.D., a member of the zoological staff of Columbia University since 1897 and, since 1924, professor of zoology, has announced his decision to retire next year. In recognition of his many years service the Pre-Medical Society of Columbia will give a testimonial banquet to Dr. McGregor at John Jay Hall on the Columbia campus, December 12.

Smallpox on Ship from African Ports.—The American-South African liner *City of New York* arrived in the New York port, November 13, with 1 case and 1 suspected case of smallpox in members of its crew. Vaccinations were started at once on the 82 crew members and 52 passengers. The 2 cases were to be removed to the Marine Hospital on Staten Island for treatment. The last case of smallpox brought into New York by ship was in 1939; another was by ship in 1937. The last locally developed case in New York was in 1932. Contacts in the recent outbreak who are residents of New York City when released by the U. S. Public Health Service will be examined daily by a department of health physician for twenty-one days. Arrangements will be made for similar supervision by local authorities for contacts wherever they go.

Medical-Dental Convention.—The eleventh annual medical-dental convention, arranged by the Joint Committee of the Organized Medical and Dental Professions of the City of New York, will be held at the Hotel Pennsylvania on December 1. Speakers will include:

Dr. Morris L. Rakiety, Bacteriophage in the Treatment of Infections of the Head and Neck.
Grace MacLeod, Ph.D., Vitamins and Diet.
Dr. Louis W. Schultz, Chicago, Treatment of Subluxation of the Cervical Joint.
Dr. [illegible], medical director, Selective Service, Wash-
ington, Aspects of Selective Service.
C. Raymond Wells, D.D.S., dental director of Selective Service, Wash-
ington, Dental Aspects of Selective Service.

There will also be a symposium on "Diagnostic Significance of Head Pains" with Drs. Joseph D. Kelly, Byron P. Stookey and Henry S. Dunning as the speakers.

NORTH CAROLINA

District Meetings.—The Sixth District Medical Society was addressed recently in Raleigh, among others, by Drs. Jerome S. Harris, Durham, on "Recent Advances in Sulfonamide Therapy" and Herman Max Schiebel, Durham, "Diagnosis and Treatment of Acute Surgical Diseases of the Upper Abdomen."—Speakers before the Ninth District Medical Society in Statesville recently included Drs. Frank B. Marsh, Salisbury, on "The Plasma Protein—Its Physiology Relative to the Normal and Failing Circulation."

Canadians Study School Health Service.—Three officials of the province of Quebec, Canada, visited in North Carolina recently to study the state school health coordinating service with the view of establishing a similar activity in Quebec. They were Hon. Henri Groulx, Pharm.D., minister of health and social welfare, Quebec and Montreal; Dr. Jean Gregoire, Quebec, deputy minister of health for the province and president of the Canadian Public Health Association, and B. O. Filteau, deputy minister of education. The visitors conferred with Dr. Walter E. Wilkins, Raleigh, state school health coordinator; Dr. John F. Kendrick, Raleigh, of the Rockefeller Foundation, adviser to the service, and others. Conferences were also held with Dr. Carl V. Reynolds, Raleigh, state health officer, and with health and education officials in Greensboro and Goldsboro. The North Carolina School Health Coordinating Service is a project of the state board of health and the state department of public instruction.

Society News.—Dr. Charles J. Andrews, Norfolk, Va., addressed the Tri-County Medical Society of Washington, Martin and Tyrrell counties at Plymouth, September 24, on "The Nausea of Pregnancy."—Dr. James F. O'Neill, Winston-Salem, addressed the Forsyth County Medical Society, Winston-Salem, September 9, on "Infusion of Blood and Other Fluids into the General Circulation by Way of the Bone Marrow Cavities."—Dr. Thomas B. Mitchell, Shelby, among others, addressed the Thermal Belt Medical Society in Shelby, October 16, on "Effective Therapy in Chronic Alcoholism."—Drs. Robert H. and Margaret E. L. Owen, Canton, discussed "Oophorhagia" (ovarian hemorrhage) before the Haywood County Medical Society in Waynesville recently.—Dr. Mark A. Griffin, Asheville, addressed the Buncombe County Medical Society, Asheville, October 6, on "Chronic Alcoholism" and Dr. Julian A. Moore, Asheville, October 20, "Regional Ileitis."

OHIO

The Farm Security Medical-Health Program.—The medical-health program of the Farm Security Administration was in operation in forty-four counties in Ohio, August 30, with about three thousand farm families participating and between six hundred and seven hundred physicians rendering services, the state medical journal reports. The so-called pooled plan is in operation in each county, the funds being contributed by FSA clients participating in the program from money borrowed from the federal government under the farm rehabilitation program. The average annual amount paid by each participating family is about \$22.

Society News.—Dr. William J. Dieckmann, Chicago, addressed the Summit County Medical Society, Akron, October 7, on "Management of the Toxemias of Pregnancy."—Dr. Richard B. Cattell, Boston, addressed the Butler County Medical Society, Middletown, recently, on "Diagnosis and Management of Lesions of the Large Bowel."—Dr. Charles D. Aring, Cincinnati, addressed the Montgomery County Medical Society, Dayton, October 3, on "Polyneuritis."—Dr. Charles E. Howard, Cincinnati, addressed the Stark County Medical Society, Massillon, September 10, on "Proctology as Related to General Practice."—Drs. George Crile Jr. and Allen Graham, Cleveland, addressed the Trumbull County Medical Society, Warren, recently, on "Diagnosis and Treatment of the Jaundiced Patient" and "Clinical Versus Pathological Malignancies" respectively.—Dr. Stanley Milton Goldhamer, Ann Arbor, Mich., addressed the Mahoning County Medical Society, Youngstown, recently, on "Diagnosis and Treatment of the Anemias."

PENNSYLVANIA

Society News.—The Lycoming County Medical Society conducted its annual clinic meeting at the Lycoming Hotel, Williamsport, November 14; speakers were Drs. Carl E. Ervin, Harrisburg, on "Early Diagnosis of Carcinoma of the Stomach"; Clayton T. Beecham, Philadelphia, "Early Diagnosis of Cancer of the Urogenital Tract"; Stanley P. Reimann, Phila-

delphia, "Experiments on Cell Division," and Roscoe W. Teahan, Philadelphia, "Considerations on the Early Diagnosis of Cancer."

Annual Postgraduate Day.—The Harrisburg Academy of Medicine will hold its annual postgraduate day in Harrisburg, December 2. Speakers and their subjects will be:

- Dr. Frank H. Lahey, Boston, Diseases of the Stomach, Duodenum and Jejunum; Modern Developments in Thyroid Disease.
- Dr. James L. Poppen, Boston, Diagnosis, Management and End Results in Herniations of the Intervertebral Disk; Diagnosis and Treatment of Brain Tumors—A Problem for the General Practitioner.
- Dr. Gilbert E. Haggart, Boston, Chronic Low Back Pain and Sciatica; Problems in Fracture Treatment.
- Dr. Elmer C. Bartels, Boston, Diagnosis and Operative and Non-operative Treatment of Hypertension; Some Medical Problems: Management of Obesity, Management of Addison's Disease, Diagnosis and Treatment of Gout.

Philadelphia

Society News.—The November 12 meeting of the Philadelphia County Medical Society was designated "Clinical Pathology Night"; speakers were Drs. Russell Richardson on "Interpretation of Clinical Laboratory Methods Useful in the Diagnosis and Treatment of Diabetes Mellitus"; William P. Belk, Wynnewood, Pa., "Clinical Pathologic Methods Useful in the Diagnosis, Classification and Prognosis of Bright's Disease," and Herbert Fox, "Value of the Tissue Biopsy to the Clinician, Radiologist and Pathologist."—The Philadelphia Laryngological Society was addressed, November 4, among others, by Dr. Edward H. Campbell on "Impressions of the Labyrinth Fenestration Operation for Deafness Gained from Three Years' Experience."—Drs. James P. Quindlen and Robert C. McElroy, among others, addressed the Obstetrical Society of Philadelphia, November 6, on "Management of Dead Abdominal Pregnancy."—Dr. Brooke M. Anspach, among others, spoke before the Philadelphia Rheumatism Society, November 6, on "Role of Gynecologic Disorders in the Production of Arthritis."

Appointments to Woman's Medical College.—Dr. Edward J. G. Beardsley, clinical professor of medicine, Jefferson Medical College of Philadelphia, has been appointed professor and head of the department of medicine at Woman's Medical College of Pennsylvania, and Dr. Benjamin Tertius Bell has been named professor and head of the department of orthopedics. Other new appointments to the faculty include:

- Dr. Clara L. Davis, Lansdowne, Pa., clinical assistant professor of medicine.
- Dr. Mary H. Easby, clinical assistant professor of medicine.
- Dr. Katherine A. Elsom, Narberth, Pa., clinical assistant professor of medicine.
- Dr. John P. North, clinical professor of surgery.
- Phyllis Bott, Ph.D., associate professor of physiologic chemistry.
- Dr. Eula Eno, associate professor of obstetrics.
- Dr. Yvonne M. Turk, clinical assistant of gynecology.
- Dr. Claire Miller, clinical assistant of pediatrics.
- Dr. John E. Eicholz, clinical assistant of psychiatry.
- Dr. Frederick Jardon, clinical assistant of psychiatry.
- Dr. Elizabeth M. Johnson, clinical assistant of psychiatry.
- Dr. J. Hamilton Allan, clinical assistant professor of orthopedics.
- Dr. Frank S. Clarke, clinical assistant professor of radiology.
- Dr. Sylvia A. Mazer, clinical assistant of urology.
- Dr. Ruth F. Harral, assistant professor of anesthesia.

New departments of anesthesia, gastroenterology and urology have been established under the following professors: Drs. Julia H. Hardin, professor of anesthesia; Mary M. Spears, professor of gastroenterology and proctology, and Faith Fetterman, professor of urology. Dr. Carmen C. Thomas has been promoted to be professor and head of the department of dermatology and syphilology. The hospital has been reorganized with Dr. Eno as medical director, and a new system has been introduced for residencies offering graduate work in medicine, pediatrics, surgery and gynecology.

SOUTH CAROLINA

Personal.—Martin D. Young, Columbia, has been appointed director of the Malaria Research Laboratory at the South Carolina State Hospital, Columbia, which is under the direction of the U. S. Public Health Service. He succeeds the late Bruce Mayne, Dr.P.H., *Science* reports.

Changes in Health Officers.—Dr. John M. Bearden is the new health officer of Laurens, succeeding Mr. L. M. Price, effective August 15.—Dr. Robert D. Hicks, Chester, has been named director of the Chester County Health Department, succeeding Dr. Walter G. Crawley Jr., Lancaster, who has been dividing his time recently between Chester and Lancaster counties, it is reported.

TEXAS

Change in Meeting Place.—The State Medical Association of Texas announces that the 1942 annual session will be held in Houston, May 11-14, instead of Corpus Christi as was previously announced. According to the state medical journal, the change was made on account of the lack of cooperation of the Robert Driscoll Hotel management in Corpus Christi.

Society News.—Dr. Jay C. Crager, Beaumont, addressed the Jefferson County Medical Society in Beaumont, September 8, on "Aviation Medicine."—Drs. Simeon H. Hulsey, Fort Worth, and Thomas M. Jarmon, Tyler, addressed the Hunt-Rockwall-Rains Counties Medical Society, September 9, on "Bronchial Asthma in the Aged" and "Common Problems in Diagnosis in Urology" respectively, and Dr. Neil D. Buie, Marlin, president of the State Medical Association of Texas, discussed "Medical Personnel and the American Medical Association."—Dr. Samuel R. Snodgrass, Galveston, discussed "Herniation of Intervertebral Disks" before the Jefferson County Medical Society in Port Arthur, October 13.

WISCONSIN

Lectures by Latin American Minister of Public Health.—Dr. Juan César Mussio-Fournier, minister of public health, Uruguay, S. A., and director of the Institute of Endocrinology, Pasteur Hospital, Montevideo, Uruguay, spoke before the University of Wisconsin Medical Society, Madison, October 23. The titles of the lectures were "Local Action of Hormones" and "The Importance of Studying the Development of the Dental and Osseous Systems in Hypothyroid Infantilism."

Annual Dearholt Day.—The second annual "Dearholt Day" was observed in Madison on November 11 under the auspices of the Wisconsin Anti-Tuberculosis Association, the University of Wisconsin Medical School and the Dane County Medical Society. Lectures were delivered by Dr. Esmond R. Long, professor of pathology, University of Pennsylvania School of Medicine, and the director of the Henry Phipps Institute, Philadelphia, and Dr. Kendall Emerson, managing director of the National Tuberculosis Association, New York. Dr. Long spoke on "Some Correlations of the Pathology and Epidemiology of Tuberculosis" and "The Roles of Environment, Nutrition and Constitution in Tuberculosis" and Dr. Emerson on "The Doctor's Duty as a Citizen" and "Voluntary Health Agency and the Physician." The special observance is held in honor of the late Dr. Hoyt E. Dearholt, Milwaukee, for many years executive secretary of the Wisconsin Anti-Tuberculosis Association.

GENERAL

Noise Abatement Group Chooses Officers.—William Reynolds, New York, was elected president of the National Noise Abatement Council at its annual meeting in New York on October 24, succeeding George P. Little, Chicago. Other officers elected include W. L. Manning, Chicago, vice president; G. L. Bostwick, Chicago, treasurer, and F. Edgar McGee, Buffalo, executive secretary. At this meeting the council announced a year round program for communities throughout the country to reduce unnecessary noise in homes, offices, industries and public places. Heretofore activities of the council have centered around local noise abatement week campaigns conducted in various communities during June.

Academy of Dermatology and Syphilology.—The fourth annual meeting of the American Academy of Dermatology and Syphilology will be held at the Waldorf-Astoria Hotel, New York, December 14-18. Special lectures will be delivered by the following guest speakers:

- Dr. Perrin H. Long, Baltimore, Clinical Use of the Sulfonamide Compounds.
- Dr. Jesse Bedford Shelmire, Dallas, Texas, Diagnosis and Treatment of Weed Dermatitis.
- Dr. Vicente Pardo-Castello, Havana, Cuba, Diseases of the Nails.
- Dr. Cornelius P. Rhoads, New York, Newer Knowledge Concerning the Chemical Causation of Cancer.
- Dr. Edward Loebholz, Philadelphia, Physiology of Pigmentation.

Symposiums and their leaders include: Avitaminoses, Dr. Paul Gross, New York; physiology and chemistry, Dr. Donald M. Pillsbury, Philadelphia; allergy, Dr. Samuel M. Peck, New York; syphilis, Dr. Udo J. Wile, Ann Arbor, Mich., and pharmaceutical therapeutics, Dr. Otto H. Foerster, Milwaukee. There will be special courses on histopathology, mycology, roentgen ray and radium therapy and photography, and many round table discussions covering various aspects of dermatology and syphilology.

New Fellowships in Nutrition.—Swift & Company, Chicago, has announced the establishment of a series of fellowships for research in nutrition. Intended to aid the federal government in its long range national program in nutrition, the fellowships provide for special research to be undertaken in laboratories of universities and medical schools with funds set aside by Swift & Company as grants in aid, beginning on November 1. The fellowships will be for one year but may be renewed when the project warrants it. Any fundamental study of the nutritive properties of foods or the application of such information to improvement of the American diet and health will be eligible for consideration for a grant. Placement of the new fellowships will be coordinated by R. C. Newton, Ph.D., and his staff of the Research Laboratories of Swift & Company, Union Stock Yards, Chicago.

Syphilis Drops with Compulsory Marriage Test Laws.—A survey by the Council of State Governments in sixteen of twenty-six states where couples planning to marry must first take blood tests shows a reduction in the syphilis rates, it was reported on October 9. The survey reported a rate of 1.28 per cent in the group taking premarital examinations. A recent estimate by the American Social Hygiene Association that the syphilis rate among the nation's adult population during the period 1935-1940 was 3.24. In making the survey, six states which have adopted premarital laws this year and four others in which these laws have been enforced for comparatively short times were excluded. According to the report, Connecticut recorded an over-all reduction from 2,494 cases in 1936 to 1,903 in 1940. Positive cases among applicants for marriage licenses in Rhode Island declined from 1.6 per cent in 1938 to 1.1 per cent in 1939 and to 0.9 per cent from July 1, 1940 to June 30, 1941. Transmission of syphilis has occurred in as many as 60,000 cases a year in the United States, according to the survey. Between 1935 and 1940 1.69 per cent, or 4,791 cases in a total of 282,667 mothers examined, showed evidences of the disease, figures of the social hygiene association revealed. Most of the antepartum blood test laws require that the tests be made within thirty days of the first medical examinations and several specify "at the same time of the first examination." Only about one third of the antepartum blood test laws provide penalties for avoidance, and few require treatment to follow positive results, so that the measures now in effect are mainly educational, it was pointed out. According to the survey of the Council of State Governments, however, positive examinations usually bring the mother back for treatment.

CORRECTION

The National Nutrition.—In the first paragraph of the letter to the editor by Dr. Logan Clendening in THE JOURNAL, September 20, page 1035, the first word in the fourth line should have been "health" instead of "wealth," and the reference to *Technology Review* in the sixth line should have been to the June 1940 issue instead of to the August 1940 issue of that periodical.

Government Services

Advisory Committee on Care of Children

An advisory committee on the daytime care of children has been set up under the Children's Bureau, U. S. Department of Labor, Washington, D. C., to work out an adequate program to care for children whose mothers are employed in defense work. The committee is composed of social workers, health officials, pediatricians, educators, nursery school people and experts in day nursing, newspapers reported. Subcommittees also are at work devising standards for procedure in day nurseries, nursery schools and recreation centers for this age level. The findings of these committees will be passed along as recommendations to state and local agencies. The creation of the committee was announced during the recent meeting of the American Public Health Association in Atlantic City by Dr. Martha M. Eliot, associate chief of the Children's Bureau. Mothers in defense industries will be able to work more efficiently, it is believed, knowing that their children are receiving proper supervision and care while they are away. Some of the important items to be developed include a well balanced feeding program, proper health supervision for these centers, and more intelligently supervised play in the day nurseries. Consideration will also be given to recreation centers for school children to fill in the gap between the time when school is out and their mothers return from work, it was said.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 11, 1941.

Food Supplies Under the Lend-Lease Act

The Ministry of Food states that the total supply of food likely to come to Britain under the lend-lease act will constitute only some 5 or 6 per cent of our total consumption, but its value is more than these figures suggest. It includes concentrated proteins, such as cheese, canned milk, dried milk, eggs, canned fish and canned meat. The canned milk forms a considerable proportion of our total supply. Food distribution is carried out by wholesalers to whom the government sells. The Ministry of Food exercises a close control over all profits, so that neither wholesalers nor retailers receive more than is adequate to cover their services. The whole price level is stabilized by the government. In the case of certain necessities, such as bread, they provide a subsidy to prevent the price rising above a certain level. The price of the more important foods is controlled, and no food received on lend-lease terms will be sold at uncontrolled prices.

Mr. Paul H. Appleby, United States Undersecretary of Agriculture, who is in this country, stated in a press interview that America was sending to Britain as much canned pork of high quality as had ever been produced there in a single year. Britain was taking a quantity of evaporated milk equal to America's former total production and dried milk in excess of the former production. Of dried eggs the quantity was a thousand times the total previous output, and the contribution of shell eggs would be 7.5 per cent of the total output of a thousand million hens. Previously America imported cheese, but now Britain was to receive 45 per cent of America's annual output. Other commodities to be sent included canned tomatoes, dried beans, fish, oils, oranges, a great quantity of lard, dried fruits and a fourth of America's salmon.

International Scientific Conference on Postwar World Order

A scientific international conference is to be held in London to demonstrate the common purpose of men of science in ensuring a postwar order in which the maximum benefits of science will be secured for all people. Among those who will preside at the sessions are the American ambassador, Mr. Winant, the Soviet ambassador, M. Maisky, the Chinese ambassador, Mr. Wellington Koo, the president of Czechoslovakia, Dr. Benesh, Mr. H. G. Wells and the president of the British Association for the Advancement of Science, Sir Richard Gregory. The conference is being organized by the British Association's division for social and international relations of science. At the end Sir Richard Gregory will put forward a new charter of scientific fellowship. Czechoslovakia, Poland, Norway, the Netherlands, Belgium and France will be represented, and exiled scientists from Germany, Austria and possibly Italy will also take part. The conference will seek to define the part which science can play in helping to secure the best use of the possibilities of the twentieth century and to make practical contributions to the solution of problems.

Anglo-Soviet Medical Cooperation

The inaugural meeting of an Anglo-Soviet medical committee was held at the rooms of the Medical Society of London. The committee has the support of the leaders of the profession, including Sir Charles Wilson, president of the Royal College of Physicians, Sir Frederick Gowland Hopkins, past president of the Royal Society, Sir Philip Manson-Bahr and Prof. J. A.

Ryle. Support has been promised by the medical branches of the navy, army and air force. Sir Alfred Webb-Johnson, president of the Royal College of Surgeons, who was elected president of the committee, said that the medical profession in this country had been intensely interested in the colossal experiment in environmental and social medicine carried out in the Soviet Republic. M. Maisky, the Soviet ambassador, said that victory in this war and peace in the future largely depends on close cooperation between Britain and the Soviet Union. He had a warm spot for the medical profession, as his father was an army doctor and his brother was also a doctor and was now in charge of a hospital. Lieutenant General Hood, director general of medical services at the War Office, said they would there welcome as much information as they could get on the medical services of the Russian forces.

The Diagnosis and Treatment of Cancer

The state in Great Britain plays a greater and greater part in the treatment of disease. At first public health legislation was confined to particular classes of the community: mothers, young children and children of school age. Then the state created organizations for the treatment of particular diseases: tuberculosis, venereal diseases and, last of all and quite recently, cancer. In 1939, just before the war, the cancer act was passed in order to ensure the earlier diagnosis and treatment of cancer. There was need for it, as many cases reached an advanced stage before diagnosis was made or adequate treatment was available. A deputation from the Royal College of Surgeons presented a memorandum to the minister of health pointing out the need for early and accurate diagnosis, increased facilities for the training of radiotherapists and the establishment of a national cancer institute. The cancer act makes provision for the diagnosis and treatment by requiring local health authorities to submit to the minister of health arrangements which secure in their areas adequate facilities for these purposes. The facilities for treatment include surgery, radium and high voltage roentgen therapy. The patients may be dealt with either in the present voluntary hospitals or in hospitals maintained by the local authorities. The outbreak of war caused the minister of health to postpone until March 1942 the coming into force of the act. This extension of time was given because of the burden of additional work thrown on the local authorities by the war. A further extension to March 1943 has now been granted, as the minister recognizes that in general it is not possible for the local authorities to make complete arrangements at the present time. But he emphasizes the importance of providing facilities for expert diagnosis and skilled treatment of all who are suffering from or suspected to be suffering from cancer.

In view of the necessity of reserving the capital and material resources of the country for works of strategic importance, local authorities are told to exclude from their interim arrangements the erection of new buildings, elaborate extensions to existing buildings or the provision of costly new equipment. But the minister considers that much can be done, even under present conditions, by extending facilities for the diagnosis and treatment of cancer; e. g., by making agreements with hospital authorities having the requisite staff and equipment, by payment of traveling expenses when necessary and by making known to the public the facilities thus provided. In some of the especially vulnerable areas, conditions may be reducing or impeding the hospital facilities available to cancer sufferers, who may thus be precluded from obtaining the treatment likely to benefit them. To counteract this the minister is endeavoring to arrange for the establishment of cancer treatment centers at certain of the hospitals in the emergency hospital scheme outside the towns which they would serve. Arrangements should be made for the transfer to them of suitable patients.

Prof. A. J. Clark—A Great Pharmacologist

The death of A. J. Clark, F.R.S., professor of materia medica in the University of Edinburgh, after an operation at the age of 56, has removed an eminent pharmacologist. Educated at Cambridge and St. Bartholomew's Hospital, he at once turned his attention to pharmacology, of which he became demonstrator at King's College, London, and lecturer at Guy's Hospital. He joined the Army Medical Service in the last great war and received the military cross for gallantry and devotion to duty. After the war he was successively professor of pharmacology at Cape Town, University College, London, and Edinburgh University. He was a member of the Medical Research Council and pharmacologic adviser to the *British Medical Journal* for twenty years. He was author of many important books, of which "Applied Pharmacology" reached a seventh edition. Others were "Comparative Physiology of the Heart," "Mode of Action of Drugs on Cells" (an original work which gained him a high reputation in other countries) and "General Pharmacology." Sir Henry Dale, president of the Royal Society, describes Clark's principal aim as "interpreting the actions of drugs in more fundamental terms." In a small popular book entitled "Fact," there appeared in 1938 from his pen the most authoritative exposure of so-called patent medicines since the British Medical Association published "Secret Remedies." He showed that the annual turnover of the trade in patent medicines was about \$100,000,000, which is nearly equal to the cost of hospital services and between twice and three times the cost of drugs prescribed by physicians. About one sixth of the advertising space in journals was devoted to nostrums. The revenue derived by periodicals from this can be imagined from the fact that eight firms which advertised remedies for nervous and digestive disorders spent \$5,000,000 annually, and a company which advertises a brand of acetylsalicylic acid stated that they proposed to spend nearly this sum in three hundred papers. When the British Medical Association issued "Secret Remedies," containing analyses, costs and the like, not only was it not noticed editorially by most papers but advertisements of it were declined by many.

BUENOS AIRES

(From Our Regular Correspondent)

Aug. 29, 1941.

Bureau of Aviation Sanitation

The national health department has petitioned the ministry of the interior to establish within the division of river and ocean sanitation a bureau of aviation sanitation. Airplanes which land in Argentina fly, in part, over extensive infected regions, where insects may easily be acquired as unwanted passengers. Besides, air passengers themselves might be infected. Aviation has greatly increased within recent years. In 1938, 771 airships carried 7,328 passengers in Buenos Aires; in 1940, 1,762 air vessels conveyed 15,845 passengers. It must also be taken into account that the period of incubation does not run its full course during the short time the passengers are on board.

Brief Reports

Prof. Dr. José Arce, professor of clinical surgery at the faculty of medicine in Buenos Aires, has resigned to devote himself completely to the study of thoracic surgery.

Dr. Delfor del Valle Jr. was appointed professor of clinical surgery at the faculty of medicine of the University of Buenos Aires to succeed Prof. R. Armando Marotta, who retired. Dr. del Valle is chief of the department in the Ramos Mejia Hospital; together with two other section heads he organized the Instituto Gastroenterología.

The Asociación Argentina para el Progreso de las Ciencias has granted a stipend to Dr. Enrique A. Viacava, assistant at

the surgical clinic of the university, which is to enable him to study the surgical treatment of cancer at the Memorial hospital in New York.

The Pan American Sanitary Bureau, in cooperation with the Rockefeller Foundation for Argentina, has provided seven stipends, which are distributed by B. A. Houssay, professor of physiology. A total of thirty-five such stipends have been planned for South America. The stipendiaries are to be attached for one year to hospitals in the United States, to extend their training.

To combat infectious abortion among cattle, Argentina has introduced certification, which is required for import as well as for export. This is to prevent the consumption of infected meat by human subjects.

A newly founded branch of the Asociación Médica Argentina is the Sociedad de Medicina Industrial in Buenos Aires. Its task is to study the dangers to the health of the worker created by fatigue, lack of cleanliness, use of toxic substances, illumination, and so on.

In July the Argentine Red Cross arranged for the shipment of food to British prisoners in Germany. The shipment consists of four hundred and eighty boxes weighing in all 22,000 Kg. The international Red Cross in Geneva will take care of the distribution. In the same manner French prisoners of war of Germany are to receive 18,400 pounds. The means for these shipments were provided by the British and French colonies in Argentina.

Society News

The American Institute for the Protection of Infancy met in Montevideo, Uruguay, under the chairmanship of Dr. Gregorio Aráoz Alfaro. Dr. Felix Brunot, delegate of the Unión panamericana, Dr. Justo González, director of the Oficina sanitaria and Miss Catharina F. Lemroot, head of the U. S. children's bureau, were among those present. To secure the cooperation of several international institutions is one of the leading objectives.

The Pan American League for the Control of Cancer will meet in 1942 in Buenos Aires. According to Francis Carter Wood of Columbia University, seventeen American countries are members of this league. A Pan American center for tuberculosis statistics is to be created. Prof. Angel H. Roffo is its president.

Deaths

Prof. Dr. Pedro Rojas, professor of embryology and histology at the faculty of medicine in Buenos Aires and director of the same institute, died on July 7 at the age of 54. He had published a book on the structure of the myocardium.

Prof. Faustino J. Trongé, who had done much for the development of obstetrics in Argentina and who was greatly esteemed in the United States, died at the age of 71 in Buenos Aires.

Dr. Pílares O. Dezeo, professor of Hygiene in the faculty of medicine in La Plata, died in Buenos Aires.

Marriages

SUMPTER WRIGHT HAWKINS, Fort Smith, Ark., to Miss Jane Elizabeth Bleiler of Mount Holly, N. J., at Abington, Pa., October 25.

RICHARD CABOT NAILING, Union City, Tenn., to Miss Marie Eleanor Dempsey of Centralia, Pa., in Boston, September 30.

JAMES E. REEDER JR., Sioux City, Iowa, to Miss Adella Gordon Badgerow of Daytona Beach, Fla., July 30.

MARCUS B. EMMONS to Miss Lillian Ha Draper, both of Iowa City, in Eldora, Iowa, August 26.

MYRON HENRY BALL, Scranton, Pa., to Dr. GLADYS FRIED of Dupont, September 7.

AARON COBLENTZ to Miss Rebecca Tauber, both of New York, October 5.

Deaths

Paul Stilwell McKibben, Ph.D., since 1931 dean and since 1929 professor of anatomy at the University of Southern California School of Medicine, Los Angeles, died, November 11, at the Good Samaritan Hospital, aged 55, following gastric resection for a malignant ulcer at the pylorus. Dr. McKibben was born in Granville, Ohio, March 14, 1886 and graduated from Denison University in Granville in 1906. He received his Ph.D. degree at the University of Chicago in 1911, where he was an assistant in anatomy from 1908 to 1911, an associate in anatomy 1911-1912 and instructor in anatomy 1912-1913. From 1913 to 1927 he was professor of anatomy at the University of Western Ontario Medical School, London, Ont., Canada, and dean from 1919 to 1927, and was associate professor and professor of anatomy at the University of Michigan Medical School, Ann Arbor, from 1927 to 1929. During the World War Dr. McKibben served as first lieutenant in the Army Sanitary Corps and did research work on brain injuries for the Rockefeller Institute for Medical Research and Johns Hopkins University. He was a member of the American Association for the Advancement of Science, the Royal Society of Canada, the American Association of Anatomists and the Society for Experimental Biology and Medicine and the History of Science Society. The University of Western Ontario granted him the degree of doctor of laws in 1928 and Denison University conferred on him the honorary degree of doctor of science in 1936.

George Albert Hendon ♂ Louisville, Ky.; Louisville Medical College, 1894; Hospital College of Medicine, Louisville, 1898; an Affiliate Fellow of the American Medical Association and member of the House of Delegates from 1928 to 1931; professor of surgery at Hospital College of Medicine from 1895 to 1908; professor of surgery at University of Louisville School of Medicine from 1908 to 1923, clinical professor of surgery from 1923 to 1934, head of the department of surgery, 1928-1929, and professor emeritus since 1938; surgeon, Louisville City Hospital and St. Anthony's Hospital; member of the Southern Surgical Association; fellow and one of the founders of the American College of Surgeons; aged 70; died, October 26, of cerebral hemorrhage and arteriosclerosis.

Max Mailhouse ♂ New Haven, Conn.; Yale University School of Medicine, New Haven, 1878; clinical professor of neurology emeritus at his alma mater; president of the Connecticut State Medical Society, 1915-1916; secretary of the state examining board from 1893 to 1900; member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease; past president of the National Association for the Study of Epilepsy; aged 84; died, October 19, of arteriosclerosis.

Wesley Franklin Kunkle, Williamsport, Pa.; Jefferson Medical College of Philadelphia, 1888; member of the Medical Society of the State of Pennsylvania; past president, secretary and librarian of the Lycoming County Medical Society; for many years school physician; for many years president of the Lycoming County Tuberculosis Society and director of the Pennsylvania Tuberculosis Society; on the staff of the Williamsport Hospital; aged 77; died, October 26, of cerebral hemorrhage.

Louis Klein ♂ Nutley, N. J.; Long Island College Hospital, Brooklyn, 1906; member of the Michigan State Medical Society; in 1935 was appointed director of clinical research of the firm of Hoffmann-La Roche, Inc.; held a similar position with Parke, Davis & Co. in Detroit, where he was on the medical staff of Harper Hospital and was consulting endocrinologist to the Wayne County Juvenile Court; aged 56; died, October 24, at his home in Upper Montclair of coronary thrombosis.

Guy Walter Luckey ♂ Austin, Texas; Barnes Medical College, St. Louis, 1907; director, local health services, Texas State Department of Health, and field director, division of county health units; at one time health officer in Bernalillo County and Albuquerque, N. M., and health officer of Boone County, W. Va.; formerly assistant city health officer, Fort Worth, Texas, and director, division of local health services; aged 58; died, October 30, of cerebral hemorrhage.

William David McDowell, Las Animas, Colo.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1901; instructor in medicine from the collegiate year 1901-1902 through the collegiate year 1906-1907 at his alma mater; member of the Illinois State Medical Society;

formerly on the staffs of the Garfield and Bethany hospitals, Chicago; aged 79; died, October 13, in the Colorado State Hospital, Pueblo, of senility.

William Sigismund Branner ♂ New Paltz, N. Y.; Medico-Chirurgical College of Philadelphia, 1906; health officer for the village of New Paltz and town of Plattekill; examining physician for the local draft board; on the courtesy staffs of the Kingston City and Benedictine hospitals, Kingston, St. Luke's Hospital, Newburgh and St. Francis and Vassar hospitals, Poughkeepsie; aged 66; died, October 26, of acute myocarditis.

Harry Cushman Willett ♂ Des Moines, Iowa; Rush Medical College, Chicago, 1894; member of the American Academy of Dermatology and Syphilology; on the staffs of the Broadlawn County Hospital, Iowa Methodist Hospital, Iowa Lutheran Hospital and Mercy Hospital; consultant in dermatology, U. S. Veterans Administration; aged 71; died, October 17, in Chevy Chase, Md., of coronary thrombosis.

Karl Albert Connell ♂ Scarsdale, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1900; at one time professor of surgery at the Creighton University School of Medicine, Omaha; served during the World War; fellow of the American College of Surgeons; formerly chief surgeon of the Presbyterian Hospital, Omaha; aged 63; died, October 18, of heart disease.

William Thomas Morrissey ♂ New Britain, Conn.; College of Physicians and Surgeons, Baltimore, 1909; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Hartford County Medical Society; served during the World War; served the New Britain General Hospital in various capacities; aged 59; died, October 23, of coronary thrombosis.

Mark Tad Morgan ♂ Captain, M. C., U. S. Army, retired, Dayton, Ohio; Ohio State University College of Medicine, Columbus, 1929; entered the medical corps of the United States Army as a first lieutenant in 1930 and in 1932 was made a captain; retired for physical disability Aug. 31, 1940; aged 39; was found dead in October at Middletown of carbon monoxide poisoning.

John Joseph Lynch, Washington, D. C.; Georgetown University School of Medicine, Washington, 1925; member of the Medical Society of the District of Columbia; instructor in clinical obstetrics and clinical gynecology at his alma mater; aged 43; died, October 25, of cerebral hemorrhage, arteriosclerosis and essential hypertension.

Joseph A. Lafferty, McKees Rocks, Pa.; Cleveland-Pulte Medical College, Cleveland, 1913; member of the Medical Society of the State of Pennsylvania; served during the World War; on the staff of the Ohio Valley General Hospital; physician for the county draft board; aged 52; died, October 13, of coronary occlusion.

John Julius La Roche Jr., Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1911; member of the South Carolina Medical Association; associate professor of medicine at his alma mater; aged 53; on the staff of the Roper Hospital, where he died, October 12, of cerebral arteriosclerosis.

Frank Joseph Donigan, Brooklyn; Long Island College Hospital, Brooklyn, 1921; member of the Medical Society of the State of New York; assistant visiting surgeon on the staff of the Coney Island Hospital and associate visiting surgeon at the Caledonia Hospital; aged 43; died, October 19, of coronary thrombosis.

John Franklin Downing, Muncie, Ind.; Medical College of Indiana, Indianapolis, 1897; member of the Indiana State Medical Association; formerly county coroner; served during the World War; on the staff of the Ball Memorial Hospital; aged 67; died, October 18, of chronic nephritis and arteriosclerosis.

Louis Daniel Retz, Walton, N. Y.; Syracuse University College of Medicine, 1920; member of the Medical Society of the State of New York; on the staffs of the Wyckoff Heights Hospital and Bushwick Hospital, Brooklyn; aged 44; died, October 23, of cerebral hemorrhage, arteriosclerosis and hypertension.

William Irenaeus Armstrong, Bellaire, Ohio; Ohio Medical University, Columbus, 1904; member of the Ohio State Medical Association; aged 65; died, October 20, in the Ohio Valley General Hospital, Wheeling, W. Va., of subdural hemorrhage due to cerebral arteriosclerosis.

John Arthur Alvarez ⊕ Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1930; fellow of the American College of Physicians; on the associate staffs of St. Joseph's Infirmary and the Hermann Hospital; aged 36; died, October 19, of fibrosarcoma of the chest wall.

Claude Alphonsus Savage, Fort Wayne, Ind.; University of Louisville School of Medicine, 1922; member of the Indiana State Medical Association; formerly county jail physician; aged 48; for many years on the staff of St. Joseph's Hospital, where he died, October 11, of coronary thrombosis.

Harvey G. Bloom, Oxford, Ind.; Miami Medical College, Cincinnati, 1895; member of the Indiana State Medical Association; formerly county coroner; aged 71; died in October at the St. Elizabeth Hospital, La Fayette, of benign hypertrophy of the prostate and cardiovascular disease.

Reuben Harold Stiehm, Madison, Wis.; Indiana University School of Medicine, Indianapolis, 1926; associate professor of clinical medicine at the University of Wisconsin Medical School; aged 40; was found dead, October 21, of acute dilatation of the heart.

Walter W. Voight ⊕ Chicago; Christian-Albrechts-Universität Medizinische Fakultät, Kiel, Prussia, 1904; fellow of the American College of Surgeons; attending gynecologist, St. Joseph's Hospital; aged 62; died, October 25, of coronary thrombosis.

Grant S. Van Horn, Batavia, Ohio; Eclectic Medical Institute, Cincinnati, 1894; member of the Ohio State Medical Association; for many years member of the school board; aged 73; died, October 16, in the Christ Hospital, Cincinnati, of uremia.

Robert Drysdale May ⊕ Jacksonville, Fla.; Emory University School of Medicine, Atlanta, Ga., 1917; served during the World War; a member of the local draft board; aged 48; died, October 6, in St. Vincent's Hospital of coronary sclerosis.

Paul Dawson Hanley, Pottstown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; on the staff of the Pottstown Hospital; aged 55; died, October 23, of uremia.

John Wiley Ruckman ⊕ West Liberty, W. Va.; Eclectic Medical College, Cincinnati, 1910; was college physician for the West Liberty Teachers College; aged 56; died, October 4, in the Ohio Valley Hospital, Wheeling, of coronary thrombosis.

James Russell Young, Pocatello, Idaho; Western Reserve University School of Medicine, Cleveland, 1917; member of the Idaho State Medical Association; fellow of the American College of Surgeons; aged 53; died, October 13, of appendicitis.

Robert Bayard Touchstone, Lytle, Texas; Memphis (Tenn.) Hospital Medical College, 1903; member and vice president of the State Medical Association of Texas; bank president; aged 65; died, October 11, of cerebral hemorrhage.

Charles Edwin Meckstroth, New Knoxville, Ohio; Starling-Ohio Medical College, Columbus, 1914; member of the Ohio State Medical Association; aged 56; died, October 20, in St. Rita's Hospital, Lima, of cerebral embolism.

Robert Russell King, Lancaster, N. Y.; University of Buffalo School of Medicine, 1931; member of the Medical Society of the State of New York; aged 33; died, October 15, in the Buffalo General Hospital of bronchopneumonia.

Albert D. Christian, Ottawa, Ill.; Northwestern University Medical School, Chicago, 1893; member of the Illinois State Medical Society; aged 73; died, October 20, in Mesa, Ariz., of injuries received when struck by an automobile.

Herman Ernest Doege ⊕ New Rochelle, N. Y.; Baltimore University School of Medicine, 1901; aged 63; on the staff of the New Rochelle Hospital, where he died, October 24, of peritonitis and ruptured diverticulum of the sigmoid.

Edgar Rae Frankish, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1904; L.R.C.P., L.R.C.S., Edinburgh, Scotland, 1905, and L.F.P.S., Glasgow, 1905; aged 61; died, October 23, of cerebral hemorrhage.

Carl Thomas Arrington ⊕ Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1930; served during the World War; aged 43; died, October 18, of an accidental overdose of sleeping tablets.

Max Peter Schranck, Twin Falls, Idaho; State University of Iowa College of Medicine, Iowa City, 1931; member of the Idaho State Medical Association; aged 39; died, October 8, in Ann Arbor, Mich., of Addison's disease.

William Franklin Bolton, Vacherie, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; member of the Louisiana State Medical Society; aged 67; died, September 22, of coronary thrombosis.

Marion Le Cocq, Portland, Ore.; University of Oregon Medical School, Portland, 1924; member of the Oregon State Medical Society; served during the World War; aged 47; died, September 18, of bronchopneumonia.

Edgar Thomas Cecil, Rainelle, W. Va.; Jefferson Medical College of Philadelphia, 1900; member of the West Virginia State Medical Association; aged 65; died, October 10, of cerebral hemorrhage and heart disease.

Theodore Brooks Breck, Cleveland; Western Reserve University Medical Department, Cleveland, 1887; aged 79; on the staff of the Glenville Hospital, where he died, October 15, of uremia and aplastic anemia.

Nils Victor Sandin, Ashland, Wis.; Chicago College of Medicine and Surgery, 1914; on the staffs of St. Joseph's Hospital and the Ashland General Hospital; aged 55; died, October 5, of coronary thrombosis.

Benjamin Lee Ashworth, Marion, N. C.; College of Physicians and Surgeons, Baltimore, 1892; member of the Medical Society of the State of North Carolina; aged 74; died, October 19, of myocarditis.

Joseph Franklin Slade, Stony Creek, Va.; Bellevue Hospital Medical College, New York, 1888; member of the Medical Society of Virginia; aged 79; died, October 14, of cardiovascular disease.

Thomas Lincoln Craig, Davenport, N. Y.; Baltimore University School of Medicine, 1892 and 1893; for many years county coroner and town health officer; aged 76; died, October 17, of myocarditis.

William Brill, Los Angeles; Columbia University College of Physicians and Surgeons, New York, 1887; aged 77; died, October 13, in the California Hospital of hemiplegia and carcinoma of the colon.

Ben Garfield Budge ⊕ Ames, Iowa; Northwestern University Medical School, Chicago, 1909; past president of the Story County Medical Society; aged 59; died in October of coronary occlusion.

Frederick Wellington Buck, Washington, D. C.; Central Medical College of St. Joseph, Mo., 1902; served during the World War; aged 68; died, October 24, of lymphosarcoma of the thorax.

Nathaniel S. Word, Camden, Ark.; Memphis (Tenn.) Hospital Medical College, 1900; member of the Arkansas Medical Society; aged 68; died, October 9, of carcinoma of the prostate.

Carl William Ekermeier, New Bremen, Ohio; Eclectic Medical College, Cincinnati, 1924; member of the Ohio State Medical Association; aged 41; died, October 11, of coronary occlusion.

Joseph Giguere, Worcester, Mass.; School of Medicine and Surgery of Montreal, Que., Canada, 1889; aged 83; died, October 16, in the City Hospital of basal cell carcinoma of the nose.

Abram B. Mosher, Bellemead, N. J.; University of the City of New York Medical Department, New York, 1879; aged 86; died, September 4, of chronic myocarditis and arteriosclerosis.

Samuel Forer ⊕ New York; Long Island College Hospital, Brooklyn, 1931; aged 36; on the staff of the Lebanon Hospital, where he died, October 11, of pulmonary embolism.

Louis A. Brandenburger ⊕ St. Louis; Marion-Sims College of Medicine, St. Louis, 1899; pathologist for the city coroner's office; aged 65; died, October 5, of carcinoma.

Orrie Lester Marks, Pittsburgh; University of Pittsburgh School of Medicine, 1908; on the staff of St. Joseph's Hospital; aged 60; died, October 9, of coronary occlusion.

Daniel Richard Lucy, Denver; Gross Medical College, Denver, 1896; formerly member of the city council; aged 81; died, October 21, of acute nephritis and myocarditis.

Albert Brueggeman, Cincinnati; member of the Ohio State Medical Association; aged 71; died, October 19, in the Good Samaritan Hospital of coronary heart disease.

Telfer Joshua Norman, Vancouver, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., 1887; aged 78; died recently of carcinoma of the prostate.

Lewis Foster Woodruff, Cedar Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1890; aged 79; died, September 29, of coronary occlusion.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Adia Tablets—As these will not bring about neutralization of hyperacidity, give relief from acid stomach, protect irritated parts or membranes of the stomach in any manner or form a protective coating over the stomach parts or membrane, the Adlerka Company of St. Paul promised the Federal Trade Commission in April 1941 to withdraw these advertising misrepresentations.

A. G. Luebert Preparations—These are put out by one A. G. Luebert of Coatesville, Pa., who signed a stipulation with the Federal Trade Commission in June 1941. In this he promised to cease representing that "Nox Em Tablets and Capsules," "Ka No Mor Capsules," "Nox Pan Tablets" and "Luebert's Laxative Tablets" are in all cases safe and harmless and to discontinue any advertisements which fail to reveal that frequent or continued use of these products may be dangerous, causing serious blood disturbances, anemia, collapse or a dependence on them and that they should not be given to children, or that "Luebert's Laxative Tablets" should not be used when abdominal pains, nausea or other symptoms of appendicitis are present, that its frequent or continued use may result in dependence on laxatives and that if a cutaneous rash appears the use of the product should be discontinued. Luebert further agreed to discontinue certain misrepresentations (not named in the stipulation abstract) regarding "Nox Em Corn Plaster," "Nox Em Jelly," "Nox Pan Tablets," "Ka No Mor Capsules," "Iron Tonic Tablets" and also misrepresentations as to the alleged value of "Nox Em Tablets and Capsules," in treating neuritis, gout, sciatica, rheumatism or stiff or sore joints.

Buellene—In April 1941 S. D. Cates, operating as Buel Company, Chicago, signed a stipulation with the Federal Trade Commission in which he agreed to cease representing that this product is effective in the treatment of falling hair or of dandruff, unless the representation is limited to assistance in the removal of accumulated dandruff scales, that his "Hot Oil Treatments" make the hair healthy or stop brittle, breaking hair or that any of his products is a hair grower.

Chelf's C C Compound or C C C C or 4C's—This product is put out by Chelf Chemical Company, Richmond, Va., and reported by the Federal Trade Commission to contain among other ingredients, potassium bromide and acetanilid. In March 1941 the Chelf concern stipulated with the Federal Trade Commission that it would cease representing that this preparation will remove the cause of headaches, indigestion or nervousness or remedy these conditions, that it may be safely used by all persons under all conditions, will not have a depressing effect on the heart and will relieve general colds or head colds, unless this representation is limited to palliative relief of aches and pains accompanying such colds. The concern also agreed to discontinue advertisements which fail to reveal that the product should not be used in excess of the dosage recommended and that its frequent or continued use may be dangerous.

Cheney Products—The G. S. Cheney Company, Boston, promised the Federal Trade Commission in April 1941 that it would discontinue certain misrepresentations in the sale of "Cheney's Nerve Phosphates" also known as "Cheney's Nerve Phosphates." Among these were that by the use of the words "Nerve" and "Nerve" or similar terms the preparation is represented as having value for bodily ailments caused by nervous disorders, that it is a food or stimulant for the nerves or relieves sleeplessness and fatigue and that its lecithin content will add to the phosphorus constituent of brain and nerve substance. The Cheney concern also agreed to cease representing that "Cheney's Vitamins Complete" is a valuable accessory to one's daily diet, unless the advertising clearly explains that the product is valuable only when there is a deficiency of vitamins and minerals which the Cheney product contains.

Circulin Garlic Pearls—These are put out by one Fred Miller, trading as the Miko Company, Long Island City, N. Y. In April 1941 Miller promised the Federal Trade Commission that he would cease advertising that this product is rich in body building materials such as manganese, sodium, calcium, iodine and phosphates has any value in relieving symptoms of nervousness, dizziness and tiredness in excess of temporarily relieving such symptoms when associated with high blood pressure or is effective in treating coughs, bronchitis or bronchial asthma.

Cliff Edwards No. 7 and No. 11—These are preparations for the hair put out by Cliff Edwards, who operates as Cliff Edwards Hair Wax, Los Angeles. In January 1941 he promised the Federal Trade Commission that he would cease representing that these products will cause hair to grow or in any way aid in growing hair on a naturally bald head, that

they are new in the sense that they consist of ingredients other than such as have long been recognized for use in scalp treatments, and that they were created by a prominent cosmetologist and dermatologist.

Corn-Go—This is no longer to be advertised as instantly stopping the pain of corns or calluses, preventing their recurrence, removing bunions or in any way proving of value in their treatment, according to a stipulation signed with the Federal Trade Commission in May 1941 by Benjamin Ingber, trading as Leonard Sales Company, Philadelphia.

Crystal-Sheen, Dandruff Eradicator and Lanoleen—These are put out by General Beauty Products Company of Chicago, of which Hec Barth, Mrs. Hec Barth and Samuel Barth are copartners. In May 1941 these persons stipulated with the Federal Trade Commission that they would discontinue certain misrepresentations. They agreed to cease using the name "Crystal-Sheen" or in any other way causing the public to confuse this hair rinse product with a competitive one, "Sparkle-Sheen," to discontinue employing any word as part of the trade name for, or any representation relating to the product "Dandruff Eradicator," so as to imply that this, when used on the scalp, will eradicate, remove or destroy dandruff or promote hair growth or feed or nourish dry scalps. The Barths also promised to discontinue using as a brand name for their emulsion the word "Lanoleen," or any other phonetic spelling of the word "lanolin," alone or in connection with other words so as to imply that their product is a lanolin product or that its lanolin content is substantial and contributes any value.

Deep-Skin Electro-Mask—As the Federal Trade Commission ruled that this device will not reestablish natural functions of the underskin, glands, circulation or nervous system, normalize the skin, revitalize the tissues, prove an effective remedy for wrinkles, crow's feet, enlarged pores, pimples, blackheads, dry or oily skin, accomplish all the benefits of the most extravagant salon facial or constitute a sure means of attaining beauty, the Commission in April 1941 announced that Inspire, Inc., of San Francisco and its president, Edgar D. Sloat, had signed a stipulation agreeing to withdraw these advertising misrepresentations. They further promised to cease using the words "Deep Skin" as a part of the brand name or representing in any manner that the effect of the device extends deeply into the skin, acts directly on the dermis or acts from the inside outward. In May 1941 the Commission accepted a similar stipulation from Kelso Norman and Louis L. Layne, trading as Kelso Norman Organization, San Francisco, an advertising agency.

Diatest Tester—This device was represented in the advertising as the only tester that does not use or require flame in determining the sugar content of urine and as the most accurate tester available for determining such sugar content. Accordingly the Federal Trade Commission in April 1941 reported that Alfred Muller, trading as Diatest Laboratories, New York, had signed a stipulation agreeing to withdraw this misrepresentation from his advertising.

Donna Lo Cosmetics—These are put out by the Donna Lo Laboratories, Inc., St. Louis, which in April 1941 promised the Federal Trade Commission that it would discontinue the following misrepresentations. That these products provide a new kind of skin care, correct skin ailments generally, permit the skin or its pores to breathe, decrease the size of the pores and cause the blood stream to circulate through inactive areas of the face. The concern also agreed to cease representing by use of the brand name "Circulation Emulsion" that this product stimulates circulation, that its "Donna Lo Face Powder" is made in France or from a French formula and that face powder sold by competitors contains ingredients which close or seal the pores of the skin.

Dr. Haines Shoes—In May 1941 the Superior Shoe Company, Inc., Chicago, stipulated with the Federal Trade Commission that it would cease employing the terms "Doctor" or "Dr." either alone or in connection with a name or with any other words as a trade name, brand or designation for its products so as to imply that they are made in accordance with the design or under the supervision of a physician and contain scientific or orthopedic features which are the result of medical determination or service.

Eldredge's (Dr.) Approved Rectal Jelly—In April 1941 Alton W. Eldredge, trading as Melrose Eldredge Company, Melrose, Mass., stipulated with the Federal Trade Commission that he would cease representing, by the use of the terms "Doctor," "Dr." or "Approved" as a part of the trade name of this product, that it has the official recommendation of doctors or pharmacists or was formulated by a physician, that it is a cure for hemorrhoids or has any effect on the symptoms of the ailment except to the extent that it may act as an astringent, provide some antiseptic action or afford the soothing effect of an emollient.

Formula X—This treatment consists of two products, "Formula X Liquid" and "Formula X Pomade," put out by Adolph R. Phillips and Daniel B. Scott Jr., trading as Adolph's Beauty Products Company, Philadelphia. In June 1941 the Federal Trade Commission accepted a stipulation from these persons in which they promised to cease advertising that these products will cause the hair to grow or will be of any benefit in treating dandruff and eczema beyond the temporary relief of itching, and that they have any merit in treating falling or brittle hair. Further, they promised to discontinue any advertisements of Formula X Liquid which fail to reveal that unless used in specified proper dilution it would cause a pronounced local inflammation or other injury.

Grace Donohue Cleanser—This is put out by Grace Donohue, Inc., of New York, which concern stipulated with the Federal Trade Commission in April 1941 that it would desist from advertising that the product is a healing agent and constitutes an efficient method for preserving a clear, smooth or attractive complexion. The firm also agreed to cease represent-

ing that the product is a remedy or cure for blackheads or whiteheads and is beneficial in the treatment of acne, crow's feet, lines under eyes or oily or dry skin. The Philip Ritter Company, Inc., of New York, which handles the advertising of the Donohue concern, signed a similar stipulation in June 1941.

Grover Graham Remedy and Graham's Butternut Pills—In April 1941 the Federal Trade Commission accepted from the S. Grover Graham Company, Inc., Newburgh, N. Y., a stipulation which promised that certain misrepresentations would be discontinued in the sale of these products. According to the stipulation, the word "Remedy" or any similar words as a part of the trade name of "Grover Graham Remedy" were to be with drawn and the preparation was no longer to be represented as anything more than a treatment to neutralize temporary excessive gastric acidity and to relieve temporarily the pain caused thereby. The concern also stipulated that it would cease advertising that "Graham's Butternut Pills" consist of a vegetable ingredient, without disclosing that it contains only the extract from a vegetable, and that it will discontinue representing that the product is a tonic or is a remedy for any disease or dysfunction or for habitual constipation, headache, biliousness and all disorders arising from inactivity of the liver or torpidity of the bowels. The Hevener Advertising Agency, Inc., of Albany, N. Y., signed a similar stipulation.

Humana Products—These are put out by Gustave Goldstein, a hair goods and cosmetic dealer trading as Humana Hair Goods and Speciality Company, New York. In May 1941 Goldstein stipulated with the Federal Trade Commission that he would discontinue advertisements which fail to reveal conspicuously certain dangerous possibilities in the use under certain conditions of "Magic Shaving Powder" and "Kongolene," and which advertisements represent that "Apex Pimento" and "Humana Dandruff Treatment" will prevent dandruff or will do more than remove such of it as has already formed on the scalp and that "Humana Dandruff Treatment" and "Amron New Hair Aid" will stop hair from falling. On three different dates in 1936 the Commission had ordered the Humana concern to discontinue certain misrepresentations in the sale of its various preparations, specifically mentioning "Magic Shaving Powder," "Ro-Zol Face Bleach" and "Requis Hair Oil."

Kaucky's Formula Herb Tea—This is put out by one Emanuel Kaucky, trading as Kaucky's Pharmacy, Berwyn, Ill. In April 1941 this person entered into a stipulation with the Federal Trade Commission in which he agreed to discontinue certain advertising misrepresentations. Among these were that the use of this product will cause one to have a clear body or a clear mind, will cause the system to return to normal, relieve rheumatism or have any value in treating headaches beyond affording relief from these due to constipation or that it is worth anything in the treatment of constipation or stomach, intestinal, bladder or kidney ailments in excess of that afforded by a laxative and diuretic.

Locao Belem—That this product will grow hair or cure baldness falling hair, dandruff and other scalp disorders rejuvenate the scalp, stimulate or revitalize hair cells and give new life to hair were misrepresentations that the Belem Products Company, Houston, Texas, promised to withdraw from the advertising, in a stipulation that it signed with the Federal Trade Commission in May 1941.

Lucky Tiger, Lucky Tiger with Oil and Sulpho-Olive Treatment—These are products of the Lucky Tiger Manufacturing Company, Kansas City, Mo., which stipulated with the Federal Trade Commission in June 1941 that it would cease advertising that either of the two first named products removes the cause of dandruff or has any value in treating it in excess of temporary removal of loose scales of dandruff, that either of these preparations will permanently stop scalp itching or as part of the "Sulpho-Olive Treatment," will reduce or prevent the loss of hair or eliminate scalp disorders and that no competing product will produce like results. The concern further agreed to discontinue the misrepresentations that "Lucky Tiger" removes the cause of or cures dry hair or that "Lucky Tiger with Oil" affects this condition in any other way than by supplementing with oil to relieve it temporarily.

Mack Brothers Products—In April 1941 Eleanor H. Mack, trading as Mack Brothers Products, San Diego, Calif., promised the Federal Trade Commission that she would cease using the word "Resuscitator" as part of the brand name for her cosmetic preparation "Revel No. 9 Resuscitator Oil" or otherwise representing that the use of this product restores life or the appearance of youth to the skin, and that she would stop employing the phrase "Pore Cleansing" as a part of the brand name of "Revel No. 1 Pore Cleansing" or otherwise representing that it will remove all foreign matter from the pores. Miss Mack also agreed to cease representing that "Revel No. 6 Lipid Cream" is of any appreciable benefit in the treatment of aged or crepey skin and that "Revel No. 16 Mouth Creme" is of value in treating bleeding or receding gums.

Ne-Wa-Tee Native Herbs—That this is an effective treatment for stomach, liver and kidney diseases and other ailments and will help the user to avoid appendicitis, catarrh, fevers, asthma, indigestion and other ailments, except as a purgative or laxative which should be sold with a caution notice, were claims which Oscar F. Fox and W. Harvey Patterson of Greenville, S. C., promised to withdraw from the advertising, in a stipulation that they signed with the Federal Trade Commission in June 1941.

Newbro, Queen and Tuxedo Preparations—These are put out by the Newbro Manufacturing Company of Atlanta, Ga., which in June 1941 stipulated with the Federal Trade Commission that it would discontinue the following advertising misrepresentations: That "Tuxedo Club Pomade" invigorates the scalp or helps the hair as nothing else will, that "Queen Hair Dressing" also designated as "New Improved Queen Hair

Dressing," is a hair grower or supplies food for the hair, that "Queen Instant Skin Whitener," also designated as "New Improved Queen Instant Skin Whitener" and as "Queen Skin Whitener Ointment" improves the tone of the complexion or retards the formation of black heads, that "Queen Skin Soap," also known as "New Improved Queen Skin Soap," helps to heal skin blemishes, that "Queen Peroxide Vanishing Cream" (or "New Improved Peroxide Vanishing Cream") imparts a fine-grained appearance to the skin, and that "Queen Cold Cleansing Cream" loosens impurities or smooths lines or wrinkles. In September 1941 the Commission announced that Cole and Company, Memphis, Tenn., an agency handling the advertising of the Newbro concern, had signed a stipulation making similar promises.

Nix Bleach Cream—In April 1941 P. Edwards, Memphis, Tenn., trading as the Nix Cosmetics Company, stipulated with the Federal Trade Commission that he would cease advertising that this cream affects the skin in a new way or in any way different from that of other preparations. In September 1941 the Commission announced that Cole and Company, Memphis, Tenn., an agency handling the Nix advertising had signed a stipulation making similar promises.

Nu-Hair—I. Orlo Johnson, E. B. Masters and Coryell Inc., all of Detroit, signed a stipulation in April 1941 with the Federal Trade Commission in which they promised to discontinue certain misrepresentations in the sale of "Nu Hair." The stipulation provided that they would cease using the brand name Nu Hair in such a way as to imply that it will grow or produce hair, that they would desist from advertising that their product represents the professional secret of a scalp specialist or is a scientific or revolutionary hair, scalp or skin preparation and is capable of preventing, removing or relieving baldness, dry or itchy scalp or of restoring the natural oils of the scalp or of controlling or helping to control the glandular activity of the scalp.

Regulator 68B—This is put out by one Felix J. Bentz, trading as Dr. Bentz Laboratory, Athol, Mass. In May 1941 Bentz promised the Federal Trade Commission that he would discontinue representing in his advertising that poisons in the blood stream are the result of undigested food stagnating or fermenting in the intestinal tract, that "Regulator 68B" is a blood cleanser, that by its use poisons will be eliminated from the system, that it regulates or stimulates the bowels, liver or digestive system to normal activity or regularity, or that its therapeutic action is other than that of a laxative or cathartic.

Ruth Clark Preparations—A stipulation was signed with the Federal Trade Commission in May 1941 by Ruth Clark, trading as Ruth Clark's Products, Los Angeles. In this she promised to cease representing, through the use of the word "Vitamin" or the abbreviation "Vit" in connection with the letter "A" in the brand name of her products "Vit A Pac," "Vitamin 'A' Beauty Cream" and "Vit A Hair and Scalp Oil" that their vitamin A content has any beneficial effect on the skin, hair or scalp or that she manufactures or compounds all the products which she sells, that her "Re-Chemicalizing Bouillon" is of value in the relief, treatment or correction of arthritis, neuritis, colds, nervousness or skin troubles or as a reducing aid of itself or when combined with "Blendavita Tea" or that the "Bouillon" has value in treating or correcting anemia or an underweight condition in excess of the benefits that may accrue from its food elements, or that it will "re-chemicalize" the system, that "Blendavita Tea" is of any value in treating kidney, bladder or skin ailments, or insomnia, or acts as an alkalinizing agent, that "Oils of Youth" will keep the body internally clean, or that "Vitamin 'A' Concentrate" would be valuable to persons suffering from frequent colds, sinus trouble or skin infections, unless the claims reveal that it would be helpful only in cases of vitamin A deficiency.

Sheer Mold Reducing Girdle—In June 1941 the Federal Trade Commission accepted from the LaVel Company, trading as Sheer Mold Company of Hollywood, Calif., and the General Advertising Agency, Inc., of Los Angeles, a stipulation that they would discontinue certain misrepresentations in the advertising of the girdle. They agreed to cease using the word "Reducing" as part of the trade name of the product and any words similar to "reducing" as descriptive of the girdle or of the results it is supposed to produce, which terms imply that the wearing of this garment will cause a reduction of local or bodily tissues or will effectively remove fat. These concerns admitted in the stipulation that though the wearing of this garment may change physical appearance by compressing that portion of the body about which it is placed it will not effectively remove fat.

Slumber Ointment—Frank D. Seiple, operating as The Nolan Company, Greenville, Pa., promised the Federal Trade Commission in May 1941 that he would cease advertising that this product is a competent treatment for ringworm in all cases or in any cases except those involving superficial ringworm infection, and that it is a remedy for athlete's foot unless it is expressly limited to superficial organisms and the relief of itching, that it is of any value in treating eczema, salt rheum, grease and rubber poisoning, cutaneous diseases or general poisoning beyond giving temporary relief from the itching which may accompany these conditions.

Vev—In May 1941 the Federal Trade Commission accepted a stipulation from R. V. Annen, trading as General Vitamins Company, Clarksburg, W. Va., in this he agreed to cease representing that "Vev" is a vitamin laxative or contains vitamins sufficient to have any therapeutic or dietetic effect, and Annen also agreed to cease representing by use of the words "erl" and "elmin" or similar ones that his product is a remedy for constipation or is of any value in treating this condition beyond that of affording temporary relief from its symptoms. He further stipulated among other things that he would cease disseminating advertisements which fail to reveal that his product should not be used when abdominal pain or other symptoms of appendicitis are present and that its frequent or continued use may result in dependence on laxatives.

SENSITIVITY TO SULFATHIAZOLE

To the Editor:—Continuing the report of Dr. Merritt H. Stiles of Philadelphia on the hypersensitivity to sulfathiazole, which appeared in *THE JOURNAL*, October 18, page 1378, I would like to join him in reporting symptoms at variance with the statement of Wein and Lieberthal (*THE JOURNAL*, September 6, page 850), in which they report only nausea and vomiting following the administration of sulfathiazole. In checking my records on the last 50 patients to whom this drug has been given in the standard dosage of different drug houses of 7.7 grain (0.5 Gm.) tablets varying from 3 to 10 tablets in twenty-four hours, I find that 6 of the patients in addition to nausea and vomiting had temperatures ranging from 102 to 104 F. and 3 of these also had a distinct cutaneous rash. These symptoms appeared after the drug had been stopped for a few days and resumed again. The symptoms appeared within the first twenty-four hours after the resumption of this medication. The symptoms subsided at once when the drug was stopped and the fever and other symptoms reappeared a few hours after the drug was resumed. Not having seen previous reports of the hypersensitivity of this drug, especially the febrile and cutaneous manifestations, I was at a loss to understand it. But since others are now reporting it and since it is evidently not generally known, I feel that my small series of cases shows a sufficiently high percentage of these complications to warrant recording, so that all facts and complications encountered with this relatively new medicament will be widely disseminated. Undoubtedly it is a wonderful and potent drug, but it evidently needs some slight change, alteration or refinement to eliminate the factor or factors causing these apparent hypersensitive symptoms.

PAUL R. STALNAKER, M.D., Houston, Texas.

HEALTH AND THE DOCTORS

To the Editor:—I wish to comment on an item under current comments on page 1269 of *THE JOURNAL* October 11.

The part which quotes the last paragraph of "Health and the Doctors," is excellent. This is the exact attitude that I have always hoped organized medicine would take. The use of "the technic of scientific experimentation to determine the actual values before general adoption" is clearly indicated.

During the past five years, I have tried to study at first hand the various forms of payment plans—both those which offer indemnification in cash and those which offer indemnification in service. Naturally I have formed certain opinions as to the effectiveness of various patterns. I am convinced that there is one very important major consideration, as yet neglected, that the "technic of scientific experimentation" will uncover, namely that payment plans will not assume major scientific and social importance until they become implements for the rational practice of health conservation and preventive medicine. When they are used to provide a method for paying physicians on a "private" and personal basis to keep the incidence and severity of disease among individuals and families at the lowest possible level, then and then only will they accomplish worth while results.

I am convinced that prepayment is a necessity in such a program because the public is not as yet well enough educated in the benefits of prevention to be willing to purchase it on a fee-for-service basis. Just what form of prepayment will do this the best I am sure I do not know at this time. However I am sure that the various types ought to be under constant scrutiny from authoritative and impartial sources and all interested should be kept posted on current progress.

KINGSLEY ROBERTS, M.D., New York.

Medical Director, Medical Administration Service.

POSSIBLE HAZARD IN USE OF OILED SILK BIB

To the Editor:—Believing that the oiled silk baby bib presents a real hazard, I submit the following report:

Susan Fuller, aged 6 months, in perfect health, was lying awake in her bed, wearing an oiled silk bib. Something prompted the mother to go upstairs to take her a toy and she found the wet bib draped over the baby's face plastered against the mouth and nostrils. Respirations had ceased and the baby was apparently dead; she was rushed across the street to my office and found to be limp, her hands were cyanotic, her face and forehead were blotchy and there was bloody froth drooling from the nostrils and mouth. Artificial respiration succeeded in reviving her; except for a few spells of coughing up mucus, her recovery was uneventful and complete.

It is suggested that, if this type of bib is used, it should be pinned to the shirt. CURTIS M. GALT, M.D., Manteca, Calif.

HAZARDS OF FIREWORKS ON CHRISTMAS AND NEW YEAR HOLIDAYS

To the Editor:—The American Medical Association has the gratitude of all who are laboring for adequate legislative control of fireworks. Your contribution in the form of the "Annual Survey of Fourth of July Accidents" is perhaps the most helpful and influential aid we have in bringing about the adoption of adequate state fireworks laws throughout the country.

The survey does have, however, one important limitation which actually tends to make more difficult the efforts to extend fireworks laws in a large section of the country. This is simply that the survey covers only the period shortly before and after Independence Day, while, in the South, fireworks are used much more extensively in the celebration of Christmas and New Year's Day. The result is that any accounting of fireworks accidents resulting from Independence Day celebrations only places the Southern states in a very favorable position as compared to their northern and western neighbors, where fireworks celebration of July Fourth is traditional and where celebration of Christmas and New Year's Day with fireworks is relatively unknown. Thus the "Annual Survey of Fireworks Accidents" in its present form may be presented in certain Southern states by the fireworks interests to show that any legislative control of this hazard is apparently unwarranted.

I feel sure that a record of fireworks accidents occurring at the time of the Christmas and New Year holidays in say a dozen Southern states would reveal the true fireworks hazard in these states and greatly facilitate efforts to reduce these accidents through proper legislative control of fireworks. We would request that the American Medical Association make such a survey during the coming holidays and suggest that the survey include the states of Virginia, Kentucky, Missouri, Tennessee, North and South Carolina, Georgia, Alabama, Mississippi, Arkansas and Louisiana.

PERCY BUGBEE, Boston.

General Manager, National Fire Protection Association.

FORMULA FOR SULFATHIAZOLE OINTMENT

To the Editor:—In the article "Sulfathiazole Ointment in the Treatment of Cutaneous Infections," which appeared in *THE JOURNAL*, October 25, we suggested as an ointment base for the sulfathiazole equal parts of hydrous wool fat and vanishing cream.

We recently have been preparing the ointment as follows: sulfathiazole 5 per cent, aquaphor (cholesterinated petrolatum) 25 per cent and cold cream 70 per cent.

We believe that the ointment base prepared with aquaphor and cold cream is more satisfactory than the ointment base prepared with hydrous wool fat and vanishing cream.

EDMUND L. KEENEY, M.D., Baltimore.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

MEDICAL CORPS, UNITED STATES NAVY

Examination. Assistant Surgeon with the permanent rank of Lieutenant (junior grade) and Acting Assistant Surgeon with the probationary rank of Lieutenant (junior grade), Jan. 5-9. Examination will be held at the Naval Hospitals at Chelsea, Mass., Newport, R. I., Brooklyn, Philadelphia, Norfolk, Va., Charleston, S. C., Pensacola, Fla., Corpus Christi, Tex., San Diego and Mare Island, Calif., Puget Sound, Wash., Great Lakes, Ill., Pearl Harbor, T. H., and Naval Medical Center, Washington, D. C. Apply Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, November 22, page 1808.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Feb. 9-11. Part III. Boston, November. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* Part I. Various centers, March 31. Final date for filing application is Dec. 31. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York City.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* April in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: New York, June. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written.* Part I. Group B. Various centers, Jan. 3. *Oral.* Part II. Groups A and B Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* March 7. Final date for filing application is Dec. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral and Written.* All Groups. Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PATHOLOGY: St. Louis, March 30-31. Final date for filing application is Jan. 30. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Philadelphia, March 30-31, preceding the Region I meeting of the American Academy of Pediatrics. Los Angeles, April 22, preceding the Region IV meeting of the American Academy of Pediatrics. Cleveland, May 13, preceding the Region III meeting of the American Academy of Pediatrics. *Written.* Locally, February 14. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF RADIOLOGY: *Oral.* All Groups. Atlantic City, June 4. Final date for filing application is April 1. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Written.* Various centers, December. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Pennsylvania July Report

The Pennsylvania State Board of Medical Education and Licensure reports the examination for medical licensure held at Philadelphia and Pittsburgh, July 8-10, 1941. The examination covered 5 subjects and included 50 questions. An average of 75 per cent was required to pass. Four hundred and fifteen candidates were examined, 399 of whom passed and 16 failed. The following schools were represented:

MEDICOLEGAL ABSTRACTS

Foods: Liability for Illness Attributed to Drinking Liquid Containing Decomposed Spider.—In 2 very similar cases decided by the court of appeal of Louisiana, the plaintiffs sued bottling companies to collect damages for injuries alleged to have resulted from drinking Coca-Cola containing decomposed spiders.

In the Hollis case, the plaintiff, after drinking a portion of the contents of a bottle of Coca-Cola, felt some foreign substance pass into her mouth. It was a slightly decomposed black widow spider. The plaintiff received prompt medical attention but was nevertheless ill for an extended period of time. The medical evidence, as described by the court, was as follows:

According to the medical evidence in the record, the symptoms possessed by plaintiff are also produced, but in a more severe form, by the bite of a black widow spider. Dr. Chambers, who was the family physician, was unable to state whether or not they were the direct result of poison from such insect that was swallowed. He was definitely of the opinion, however, that her illness was brought about by the spider's presence in the drink, for, as stated by him, "she was not sick before she took it, and she got sick, and so acutely, afterwards."

The defense expert, Dr. A. G. McHenry, was of the belief that poison from a spider, if swallowed, would be destroyed by gastric juices and enzymes of the stomach, and no pernicious infection would result therefrom. He attributed the symptoms possessed by plaintiff to the expiring of her menopause, and to other causes. By the latter phrase was meant "from having taken something that she regarded unclean in her mouth", and he thought that shock and unpleasantness, such as would superinduce vomiting or nausea of different degrees of severity in different individuals, attended the taking. It was his opinion, however, that "a normal individual should be over the effects in a week."

The plaintiff obtained a judgment in the trial court and the defendant appealed to the court of appeal of Louisiana, second circuit.

In the Jenkins case, the plaintiffs, husband and wife, had also purchased bottles of the drink in a local drug store. Immediately after the wife's first swallow, taken through a straw, she became ill and nauseated. She was taken to a physician for treatment and subsequently recovered. In the physician's office, some thirty minutes after the wife had taken her first sip of Coca-Cola, the contents of the bottle were examined. They were found to contain portions of two disintegrated spiders of unstated variety. The medical evidence in this case, as described by the court, was as follows:

Dr. Ward testified that he examined Mrs. Jenkins shortly after she came upstairs and found rigidity of her abdominal muscles, raising of her eyebrows and nausea. Jenkins and his wife, without being asked by the doctor, told him that they had been drinking coca cola. This shows clearly that they then suspected that the coca cola had caused Mrs. Jenkins' illness, or else they wanted Dr. Ward to suspect this as a cause, and yet, despite this knowledge on their part, the husband was insisting on his wife drinking more of this coca cola to settle her stomach. Some thirty minutes after Jenkins and his wife had been in the doctor's office (during all of which time the bottle had been in the possession of Mr. Jenkins and had been uncapped since it was first opened in the drug store) Dr. Ward poured out the contents of the bottle into a pan and found what to him looked like portions of two disintegrated spiders which appeared to have been in the bottle for some time.

While Dr. Ward described Mrs. Jenkins' symptoms as those of a spider bite, except for the vomiting, he could not say that her illness was caused from anything she drank from the bottle nor from any poisonous substance. He expressed the opinion that a person could absorb poison by swallowing a spider, yet he was not sure of this as he had had no experience along that line. Mr. C. L. Clay, a toxicologist employed by the State Health Department, testified that, in his opinion, the swallowing of part of a spider would not cause the symptoms which Mrs. Jenkins had; that the poison or venom of a spider, if swallowed, would be digested as other food and would not get into the circulatory system unless there was some cut or abrasion in the mouth, throat or stomach through which it could be absorbed.

From an adverse judgment in the trial court, the plaintiffs appealed to the court of appeal of Louisiana, first circuit.

In the Hollis case, the court of appeal said that the manufacturer of bottled beverages is chargeable with knowledge of the contents of the bottles it sells for public consumption and that if ill effects follow the drinking of such contents the manu-

facturer is liable for injuries which result. The court further said, however, that the plaintiff was required to prove that her injuries were the proximate result of the defendant's acts and that such proof should be carefully scrutinized because the manufacturer usually has no eye witnesses to the occurrence. The court concluded that the evidence clearly showed that the bottle had not been tampered with before it was purchased by the plaintiff. Coca-Cola becomes flat a short time after the cap is removed because of the loss of carbon dioxide. The plaintiff testified that it was sparkling when she started to drink. The court of appeal, therefore, held that the plaintiff had sustained her burden of proof and affirmed the judgment in her favor.

In the Jenkins' case, the court said that the plaintiff was required to prove with certainty that the bottle contained some deleterious substance, that the substance did not get into the bottle after it left the defendant's plant and that the plaintiff swallowed some of the substance and that it made her sick. The evidence showed, the court pointed out, that the plaintiff told her husband after one swallow that she thought the Coca-Cola was making her sick but that she continued to take two or three more swallows after that. Though she became nauseated, neither she nor her husband complained to the drug clerk that her sickness was caused by something in the bottle. Finally, the court found that the bottle had been uncapped and in the husband's possession for at least half an hour before its contents were poured out and examined. The court considered it unreasonable to believe that the wife could have gotten enough poison to cause her illness in view of the fact that she drank only through a straw which would have prevented her from drawing in any but the smallest particles of a foreign substance. The court of appeal was of the opinion that the plaintiffs had failed to prove by clear and convincing evidence that the wife's illness was actually due to the drink, and the judgment for the defendant was accordingly affirmed.—*Hollis v. Ouachita Coca-Cola Bottling Co., Ltd.*, 196 So. 376 (La., 1940); *Jenkins v. Bogalusa Coca-Cola Bottling Co., Ltd.*, 1 So. (2d) 426 (La., 1941).

Federal Food, Drug and Cosmetic Act: Allegedly False Advertising Not Accompanying Actual Shipment of Product as Misbranding.—The defendant shipped certain vitamin products in interstate commerce. Apparently, separate and apart from the actual shipment of the vitamin products, the defendant sent to distributors of those products certain literature and advertisements, allegedly falsely representing that the products would cure a list of stated human ailments, which by the directions of the defendant the distributors were to place on their walls and shelves in proximity to the vitamin products offered for sale. The United States government, alleging that the literature and advertisements so separately shipped constituted misbranding of the vitamin products in violation of the Federal Food, Drug and Cosmetic Act, sought to enjoin the defendant from shipping such allegedly misbranded products in interstate commerce.

The government and the defendant stipulated that prior to the trial of the action the trial court should determine whether or not certain paragraphs of the bill of complaint, which paragraphs alleged facts substantially as noted, state a claim on which relief can be granted as against the defendant. Consequently, the sole question for the determination of the trial court, the district court, eastern district, Wisconsin, was whether the act of bringing written, printed or graphic matter containing false and misleading therapeutic claims in the presence of, proximity of or in association with an article, after shipment in interstate commerce, was a misbranding of that article within the meaning of the term "misbranding," as the term is used in the Federal Food, Drug and Cosmetic Act. That act, the court pointed out, provides in section 352(a) that a drug is deemed misbranded if its labeling is false or misleading in any particular, and section 321(m) defines labeling to mean "all labels and other written, printed or graphic matter (1) upon any article or any of its containers or wrappers, or (2) accompanying such article." In determining, said the court, the intent of Congress in enacting the two subsections just noted, the legislative history of the act in question should be considered.

The bill which on enactment became the Federal Food, Drug and Cosmetic Act, as introduced gave jurisdiction for its enforcement to the Department of Agriculture. While the bill was pending and possibly because of the desire of the Federal Trade Commission to enforce any provisions as to false advertising, a separate measure was passed (Public Act No. 447, 52 Stat. 111, 15 U. S. C. A., section 41) specifically giving jurisdiction over false advertising of foods, drugs and cosmetics to the Federal Trade Commission. Thereafter the Federal Food, Drug and Cosmetic Act was enacted giving jurisdiction to the Department of Agriculture to enforce the provisions as to adulteration, packaging and labeling, but the enforcement as to false advertising remained in the Federal Trade Commission. As this action was brought under the Federal Food, Drug and Cosmetic Act this court cannot here be concerned with any false advertising by the defendant, and the sole question to be determined is whether or not there was a misbranding by false or misleading labeling. The government necessarily contends for an extremely broad interpretation of the language of the act defining labeling, as noted. The government argues that when Congress said "accompanying such article," in section 321(m), which reads, in part, "The term 'labeling' means all labels and other written, printed, or graphic matter . . . (2) accompanying such article," it did not necessarily mean accompanying in the ordinary sense of the word as long as the literature eventually came together with the products before or when offered for sale. Congress, continued the court, did intend that labeling should be something more than the printed or written matter actually affixed to the article itself. It undoubtedly had in mind the practice of manufacturers of placing circulars and printed matters in cartons, which literature would not be affixed to the product to be sold. However, it would be a case of legislation by judicial construction to say that literature "placed on shelves, display counters, or in window displays" comes within the definition of labeling. It is advertising, pure and simple. The Congress could have provided that all written or printed matter displayed near or in proximity to the article was labeling; but it did not do so. Suppose the defendant provided a sign, extolling the virtues of his product, to be hung on the wall. Under the construction contended by the government, it could be considered labeling. What about a billboard across the street? At what point could a line be drawn where labeling would end and advertising begin? In view of the fact that Congress decided that evils in the field of advertising as to foods, drugs and cosmetics were to be handled by the Federal Trade Commission and the Federal Food, Drug and Cosmetic Act was therefore amended accordingly, there is no justification for any court to put a strained and unnatural construction on the term "labeling." Furthermore the Federal Food, Drug and Cosmetic Act is a criminal statute. Statutes creating and defining crimes are not to be extended by intentment because the court thinks the legislature should have made them more comprehensive. In the opinion of the court, therefore, the material paragraphs in the bill of complaint did not state a claim against the defendant on which relief could be granted.—*United States v. Lee*, 40 F. Supp. 801 (Wis., 1941).

Hospitals: Res Ipsa Loquitur as Applied to Ailment Following Childbirth.—The plaintiff sued the defendant hospital, alleging that after she was admitted to the hospital to be delivered of a child "twilight sleep" was administered and that while she was in the delivery room, unconscious, unknown agents and employees of the hospital negligently permitted portions of her body to strike against some unknown substance, thus causing, as she ascertained when she regained consciousness, two or three knots or sore spots on her head, severe headaches and soreness in her arms to the extent that she temporarily lost their use. At the trial, the patient's private physician, who had delivered her, stated that while she was in the delivery room she did not fall off the delivery table or bump her head and that nothing had happened or could have happened in the delivery room to account for her complaints. The knots, or sore spots, on her head, he testified, were not the result of an injury, since "to be from an injury there must

be a clot under the scalp," and in his treatment of the plaintiff he saw no such clot but observed a secretion which is found in an eczema "which can come from some infection; and sometimes they just come without any provocation." In his opinion, "the trouble he found on her head was an eczema." The soreness in her arms he attributed to her grasping, while unconscious, handles provided in the delivery room for such patients "to pull on." Relatives of the plaintiff testified as to their presence in the patient's room from the time she was returned from the delivery room until she regained consciousness and that in that period she did not fall out of bed or bump her head. At the conclusion of the plaintiff's case the trial court granted a nonsuit and the plaintiff, in effect, appealed to the court of appeals of Georgia, division 1.

The plaintiff apparently argued on appeal that the action of the trial court in granting a nonsuit was improper because the doctrine of *res ipsa loquitur* was applicable under the circumstances—that is, from the facts here present an inference of negligence on the part of the hospital should have been drawn. We do not think the doctrine of *res ipsa loquitur*, said the court, is applicable to the facts of this case. Consequently proof that three knots arose on the head of the patient after she became an inmate of the hospital, that she was unconscious a part of the time, that she suffered a severe pain in her head after the birth of the child and that she temporarily partially lost the use of her arm would not, without more, establish the fact that the hospital was negligent in allowing the patient's head to strike something, such as a part of the bed or the floor. Especially is this so when the plaintiff's physician gave it as his professional opinion that the knots were the result of eczema, that among other things the fluid which came out of the knots was not such as would have come from them had they been caused by a blow, and that they were not the result of a blow or any injury, that the headaches complained of frequently followed childbirth and, in his opinion, were not the result of a blow, and that the trouble involving the arm was common in childbirth cases and was not the result of any injury. As was said in *Georgia Ry. & El. Co. v. Harris*, 1 Ga. App. 714, 57 S. E. 1076, 1077:

When the party upon whom the burden of an issue rests seeks to carry it, not by direct proof, but by inferences, he has not, in this reasonable sense, submitted any evidence for a jury's decision until the circumstances he places in proof tend in some proximate degree to establish the conclusion he claims; and for this the facts shown must not only reasonably support that conclusion, but also render less probable all inconsistent conclusions.

Applying this rule to the facts in this case, we do not think that, admitting the circumstances proved and all reasonable deductions therefrom, the plaintiff showed any negligent conduct on the part of the hospital as alleged in her petition. The court of appeals accordingly held that the trial court had not erred in granting a nonsuit and affirmed the judgment in favor of the hospital.—*White v. Executive Committee of Baptist Convention*, 16 S. E. (2d) 605 (Ga., 1941).

COMING MEETINGS

- Annual Congress on Industrial Health, Chicago, Jan. 12-13. Dr. C. M. Peterson, 535 North Dearborn St., Chicago, Secretary.
- American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Diveley, 1103 Grand Ave., Kansas City, Mo., Secretary.
- National Society for the Prevention of Blindness, New York, Dec. 4-6. Mrs. Eleanor Brown Merrill, 1790 Broadway, New York, Executive Director.
- Puerto Rico, Medical Association of, Santurce, Dec. 11-14. Dr. David E. Garcia, P. O. Box 3866, Santurce, Secretary.
- Radiological Society of North America, San Francisco, Dec. 1-5. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Society for the Study of Asthma and Allied Conditions, New York, Dec. 6. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Society of American Bacteriologists, Baltimore, Dec. 29-31. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Southern Surgical Association, Pinehurst, N. C., Dec. 9-11. Dr. E. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Surgical Association, St. Paul, Dec. 5-6. Dr. Arthur R. Metz, 2449 Washington Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Endocrine Therapy as Applied to Gynecology. R. W. TeLinde, Baltimore.—p. 81.

*Novocain Sympathetic Block Method of Therapy in Thrombophlebitis. M. DeBaKey and A. Ochsner, New Orleans.—p. 87.

*Management of Patients with Appendicitis, with Special Reference to Those with Perforation. C. N. Carraway, Birmingham.—p. 91.
Diagnosis and Treatment of Preeclampsia. R. Emens, Decatur.—p. 99.
Drugs in Infancy and Early Childhood: Dosage and Accurate Administration. R. E. Cloud, Birmingham.—p. 102.

Sympathetic Block for Thrombophlebitis.—DeBaKey and Ochsner believe that the best method of treating thrombophlebitis is the production of vasodilatation by blocking the regional sympathetic ganglion with procaine hydrochloride. The method is based on the concept that vasospasm resulting from impulses originating from the thrombosed venous segment is one of the most important factors in producing thrombophlebitis. The edema of the extremity in a patient with phlegmasia alba dolens should disappear within a relatively short time after sympathetic ganglion block. Similarly the other manifestations are also probably relieved by the increased vascularity. The dramatic relief of pain is probably due to the increased blood supply, the pain being the result of ischemia. The rapid subsidence of fever may also be explained on the basis of a more rapid resolution of the inflammation because of the increased vascularity to the involved venous segment. The pain of 85 per cent of 41 patients so treated was completely and permanently relieved within from fifteen to thirty minutes after the first injection and in the rest after the second injection. More than 60 per cent of the patients were free from fever within forty-eight hours. The temperature of all but 2 patients returned to normal within seven days. There was complete subsidence of edema within four days or less in 50 per cent of the patients, within five to eight days in 30 per cent and within nine to ten days in 15 per cent. This method of therapy shortened the period of convalescence and hospitalization. Approximately 90 per cent were discharged within twelve days. The sites of puncture for the lower extremity are determined by marking points approximately two and one-half fingerbreadths lateral to and horizontal with the spinous processes of the first four lumbar vertebrae. Each needle is inserted vertically until the transverse process is reached; its direction is then changed slightly toward the midline and it is inserted about two and one-half fingerbreadths beyond the transverse process, so that its point is near the anterior lateral surface of the body of the vertebra, where the sympathetic chain lies. Procaine hydrochloride, 5 cc. of a 1 per cent solution, is injected at each site. Blocks, two or three, should be done daily until the temperature drops to and remains normal. Radical treatment, ligation or excision of the involved venous segment or ligation of the vein proximal to a thrombophlebitic process, is rarely necessary.

Appendicitis.—Carraway states that since 1923, when the surgical staff and other members of the Norwood Clinic began to make a careful study of patients with appendicitis in an effort to lower the mortality, there has been a steady decrease in mortality. The decrease has been most definite during the last five years (0.31 per cent in all types of appendicitis). The decrease is a reflection of the great reduction of cases of rupture and abscess (from 30.8 to 3.4 per cent). Omitting 2 cases of abscessed appendix in which the diagnosis was not confirmed at operation or necropsy there have been only 2 deaths among 116 patients with perforated and/or abscessed appendixes, a mortality of 1.72 per cent during the last five years, during which immediate operation was always advocated. The author believes

that the following factors have helped to lower the mortality: (1) correct taking of the history and careful physical examination permitting an early diagnosis, (2) insistence that the family physician not procrastinate and if he is doubtful that he get a competent consultant, (3) recognition of the fact that in the patient whose onset of symptoms is severe and the cycle completed in a short time the appendix is more likely to become gangrenous and to rupture, making delay in operation unwise, (4) rigid postoperative care, especially of the patient with a ruptured appendix and (5) the assignment of patients with peritonitis to only the most thoroughly trained and experienced surgeons.

Fetal Electrocardiography. H. Mann and P. Bernstein, New York.—p. 390.

Wolf-Parkinson-White Syndrome, with Paroxysms of Ventricular Tachycardia. S. A. Levine and P. B. Beeson, Boston.—p. 401.

Blood Picture in Rheumatic Fever.—Wasson and her associates studied in detail the blood of 100 hospitalized children with acute rheumatic fever. The study reveals that blood determinations if frequently and accurately repeated give a correct index of the status of a rheumatic child. The study corroborates the prevailing opinion that the erythrocyte sedimentation rate is the most delicate nonspecific indication of rheumatic infection. However, allowance must be made for the premenstrual period and for acute anemia. The mean erythrocyte sedimentation rate of menstruating girls is higher than that of puberal girls and boys. When an infection of the upper part of the respiratory tract ushered in an attack of rheumatic fever, the erythrocyte sedimentation rate would rise and remain accelerated or it would continue to rise after the symptoms of the cold had subsided. Single erythrocyte sedimentation rates are of negligible, if of any, value. It takes the erythrocyte sedimentation rate on an average of two months to return to normal in acute rheumatic fever; if a rise becomes normal in a few days or even two weeks the patient has had an infection other than rheumatic fever. The nonfilamented neutrophil count is not so sensitive as the erythrocyte sedimentation rate, but it has the advantage that an increase in the nonfilamented cells always heralds an infection, and often a severe one. During acute attacks of rheumatic fever the nonfilamented cell count closely parallels the sedimentation rate, except in the terminal stages, when it returns to normal sooner. A normal Schilling count does not mean that infection is absent, but that the infection either is trivial or is just beginning and that as yet it has had no effect on the bone marrow. A single hemoglobin level determination is an unreliable standard of activity. Only the trend of the hemoglobin curve has significance. Of a total of eight hundred and twenty-three blood platelet counts, 66.93 per cent were below 200,000, and only 4.38 per cent above 250,000. This sharply subnormal platelet count in children subject to rheumatic fever characterizes the quiescent as well as the acute stage of the disease. An acute infection produced a sharp decrease in platelets only toward the end of the attack, and then a rapid rise. The bleeding and coagulation times had no diagnostic significance. Capillary resistance was important in the diagnosis of the rheumatic state. The lowest capillary resistances were observed in children who had had repeated attacks of epistaxis. The lowest erythropermeability occurred during the spring

months, when attacks of rheumatic fever are most frequent. The hemorrhagic tendency of the rheumatic state may be explained by (1) the generally low blood platelet level with further reduction during the acute phase and (2) the increased capillary erythropermeability of all patients with rheumatic fever, especially those prone to nosebleeds and acute attacks of fever.

Occlusion of Coronary Arteries.—According to Blumgart and his collaborators, experiments were performed on 39 dogs to learn whether temporary occlusion of a coronary artery would produce myocardial infarction and persistent electrocardiographic changes characteristic of myocardial ischemia. In 12 of 18 animals allowed to survive four or more days electrocardiographic changes typical of myocardial ischemia were found during the first few days to weeks after occlusion of a coronary artery for five to forty-five minutes. The type of change varied according to whether the occlusion was in the anterior descending or left circumflex artery. Eight animals died of ventricular fibrillation during the first five minutes of occlusion or when the circulation was reestablished after fifteen to thirty minutes of occlusion. No gross evidence of myocardial infarction was found in the 7 animals that lived for four to forty days after occlusion for five to twenty minutes. There was gross evidence, proved subsequently by microscopic examination, of infarction in 8 of 11 experiments in which occlusion was maintained for twenty-five to forty-five minutes. The extent of infarction was roughly in proportion to the duration of the arterial occlusion. The experiments indicate that temporary ischemia may cause irreversible myocardial changes and, if the ischemia is of sufficient duration, may cause myocardial infarction similar to that which occurs after permanent and complete occlusion of an artery. In man, pathologic observations indicate that an inadequate blood supply over a prolonged time may cause the same myocardial changes as complete ischemia of shorter duration. The focal areas of fibrosis commonly found in the hearts of patients with angina pectoris and those areas of the hearts of dogs subjected to temporary ischemia seem to have a common underlying pathologic physiologic mechanism. Angina pectoris is the clinical expression of temporary, relative, myocardial ischemia. The cardiac pain of some patients is more prolonged than that consistent with angina pectoris, but the clinical evidence of myocardial necrosis is absent and a diagnosis of angina pectoris or acute myocardial infarction would be erroneous. Coronary failure and angina pectoris seem to have the same physiologic basis. The experimental, clinical and pathologic data regarding "silent infarction" of the myocardium suggest that the areas of fibrosis were not completely occluded. The authors believe that the experimental data obtained are applicable to the phenomenon of cardiac infarction in the absence of complete occlusion of a coronary artery in man.

Digestive Disorders in Soldiers.—Hurst points out that most soldiers admitted to hospitals in England for gastric or duodenal ulcer have had attacks before joining the army. The recurrence appears to be due to the change from the compara-

tively strict civilian diet to the heavy army food. Psychologic factors have had little, if any, importance in the British Expeditionary Force, but this was not true among soldiers serving in England. Symptoms recurred in 70 per cent within two months and often within a few days, and in the remainder within eight months after enlistment. Among soldiers with ulcer, the teeth of 38 per cent were inadequate for chewing. The author believes that no man who presents definite evidence of having had an ulcer should be accepted for service. He should be rejected even if he has been free of symptoms for a long time as the ulcer diathesis is always present and it makes him liable to recurrences especially when his strict civilian life is replaced by the comparative hardships of military service. Dyspepsia alone should not be a reason for rejection. Soldiers with mild dyspepsia should not be hospitalized but treated by reassurance and alkali mixtures by their regimental medical officers. Those with severe dyspepsia of long standing should be treated at hospitals, and when ulcer, gastritis, cholecystitis and other possible organic causes have been excluded, the dyspepsia can be regarded as functional, except in malingerers. The tendency in the army to call all functional gastric disorders "gastritis" is a mistake. Gastritis is an organic disease, it is most undesirable to confuse it with functional gastric disorders with no organic basis. If an ulcer is diagnosed the soldier should usually be invalided from the service. An exception may be made for officers and other men with important sedentary duties, for whom provision can be made for regular well cooked meals and intermediate feeds. Functional dyspepsia should be treated immediately and the soldier's ability to eat ordinary army food and face ordinary army life restored. The recognized malingerer should be sent back to duty. Delay in proper treatment and disposal is likely to produce "disordered action of the stomach" corresponding to "disordered action of the heart" or the "effort syndrome." Both conditions are genuine enough, but they are the product of bad treatment and not of army life. The author believes that much man power would be saved if special army units, as suggested by Schindler, staffed by medical officers experienced in gastroenterology, clinical pathologists and expert roentgenologists would be established. Such units would recognize at least 95 per cent of chronic gastric and duodenal ulcers. The unit should have three distinct divisions: division A for diagnosis, division B for patients suffering from organic disease and division C for those suffering from functional dyspepsia. A few patients admitted into division C might be hopelessly hypochondriacs, who should be discharged from the army without pensions.

Hereditary Hemorrhagic Telangiectasia.—Griggs and Baker report the 3 cases of multiple telangiectasia with gastrointestinal bleeding encountered at the Los Angeles County Hospital during the last twelve years. The diagnosis of hereditary hemorrhagic telangiectasia is usually not difficult, telangiectatic lesions on the skin and mucous membranes, the definite tendency for the lesions to bleed and a positive family history comprise the diagnostic criteria. Information regarding the family history of the first patient is meager, but a negative history would not militate against the diagnosis, since Fitz Hugh has pointed out that the disease may skip one or more generations. Two of the patients first noticed symptoms toward the end of the fourth decade. Gastrointestinal bleeding rarely occurs before this, but nasal bleeding is not unusual in the teens. The sexes are equally affected. The disease may be transmitted by either sex. The spleen of 1 patient and the spleen and liver of another patient were enlarged. The patient with the enlarged spleen had two severe transfusion reactions. The mortality of the disease is low, but death from spontaneous hemorrhages from a telangiectatic area may occur. Several instances of such deaths occurred in the families of the patients reported on. Severe bleeding is ascribed by Steiner to the absence of elastic tissue in the dilated vessels of telangiectatic areas. Familial multiple telangiectasia should be considered in all cases of obscure gastrointestinal bleeding. Gastrointestinal hemorrhage frequently causes abdominal discomfort. All 3 patients at times had some abdominal distress, especially during active bleeding.

Sulfanilamide for Otitis Media.—Braun and Bigler determined the value of chemotherapy for acute otitis media by treating half of 425 children with this condition with sulfanilamide and symptomatic treatment and the other half only by symptomatic treatment. The ages of the patients varied from 2 weeks to 13 years. Both ears of 238 patients were involved, so that 663 ears were treated. The average duration of otorrhea was eleven and fifty-eight hundredths days for the patients given sulfanilamide and twenty and forty-three hundredths days for the controls. Myringotomy, indicated by sustained fever, severe earache and bulging of the tympanic membrane, was performed on 33 of the patients treated with sulfanilamide and on 50 controls. The most significant difference among the two groups was the incidence of complications; there were 12 instances of surgically proved mastoiditis among the controls and only 4 among the patients given sulfanilamide. This made complicating mastoiditis three times as prevalent among the controls as among the specifically treated patients. There were no fatalities in either group. The results suggest that careful, adequate and sufficiently sustained sulfanilamide therapy should be tried early in all cases of acute otitis media.

Serum Reactions.—Top and Watson used "despeciated" diphtheria antitoxin for 61 patients and "despeciated" scarlet fever antitoxin for 69 patients. Despeciated indicates that the proteins of the antitoxin are so altered that specific biologic reactions to horse serum were prevented when tested on laboratory animals. The antitoxin molecule is altered only slightly, but the alteration is enough to change its biologic specificity without impairing its antitoxic or antibacterial properties or its potency. The authors' experience coincides with that of others who have used "despeciated" antitoxins in that they found that allergic reactions were greatly reduced. The immediate advantages of "despeciated" serums are threefold: 1. Most patients who are very sensitive to ordinary serums may now be treated effectively. 2. The incidence of all serum reactions can be greatly reduced. 3. It seems probable that serotherapy may now be given to certain patients to whom it was formerly denied. The question whether the hesitancy to use serotherapy in moderately severe scarlet fever because it may preclude the use of diphtheria or tetanus antitoxin later on is removed by "despeciated" antitoxins remains to be answered by additional clinical information, particularly by the tolerance of patients to the readministration of these antitoxins at intervals of months or years. Published reports indicate that the incidence of all reactions (allergic) with the use of the new antitoxins is less than 10 per cent as compared with a control incidence of 40.5 per cent among 2,675 cases reported by Fox and 43.6 per cent among 87 controls given regular antitoxin by Toomey and Kimball.

Absence of Right Lung.—Van Loon and Diamond report the case of an otherwise healthy child who presented unmistakable evidence of congenital absence of the right lung. Other than Munchmeyer's clinical diagnosis of unilateral pulmonary agenesis shortly before the death of his 2 year old male patient with pneumonia, subsequently verified at postmortem examination, the authors believe that theirs is the first clinically authentic case. Their patient is a girl 3½ years of age, with a normal developmental history, who except for several transient episodes of illness, characterized by a profuse nasal discharge, a mild cough and, at times, noisy breathing, has always been in excellent health. During one of these episodes of illness the first roentgenograms of the chest were made and their appearance prompted the attending physician to advise hospitalization for further study. At present there is no evidence that she has any other congenital anomaly. The pulmonary anomaly consists of absence of the right main stem bronchus and lung and narrowing of the lower end of the trachea. Roentgen study indicates that no pulmonary vessels are present on the right side, but proof must await demonstration at necropsy. The patient's prognosis, barring extensive disease of the left lung, appears to be good. There is no reason to believe that the child's future course will be adversely affected by her pulmonary aplasia. Heerup's report of a similar congenital defect in a woman of 72, who died of cerebral hemorrhage, indicates that the condition is compatible with longevity.

Human Equine Encephalomyelitis.—Buss and Howitt state that since 1939 a different point of view has obtained concerning the neurotropic diseases (equine encephalomyelitis and poliomyelitis) in Kern County, Calif. Although poliomyelitis predominated, an unexpectedly high proportion of the cases were equine encephalomyelitis and a few were the St. Louis type of encephalitis. This was demonstrated by serum neutralization

tests. A few remained undiagnosed. Thus it has been shown that more than one variety of neurotropic virus disease is prevalent in the county. In 1938 71 patients, in 1939 160 and in 1940 85 patients were admitted to the Kern County General Hospital with a tentative diagnosis of neurotropic virus disease. On the basis of neutralization tests, epidemiologic histories and clinical and laboratory observations 116 patients were segregated as having equine encephalomyelitis; 22 in 1938, 46 in 1939 and 48 in 1940. The western equine virus was recovered from the brains of 2 patients. Of 112 specimens of serum obtained during the three years from patients with a diagnosis of encephalitis, 97 (86.6 per cent) and of 82 specimens of serum from patients with a diagnosis of poliomyelitis 5 (6 per cent) neutralized the equine virus. Among 82 well contacts, the serum of only 6 (7.3 per cent) showed evidence of neutralizing ability; the serum of 5 was weakly positive and of 1 was strongly positive. The serum of 41 sick contacts was tested for neutralizing ability and that of 29 (70.7 per cent) was positive for the virus of equine encephalomyelitis. That so many of the sick contacts really had a mild form of the same disease is suggestive of a common source of infection or exposure to similar environmental conditions, especially as many of them lived on farms, in labor camps, in box cars or in small towns where there was an abundance of mosquitoes. Males were predominant among patients with poliomyelitis or encephalitis and the largest percentage of patients with a diagnosis of encephalomyelitis in all three years were children less than 10 years of age. Equine encephalomyelitis began about May, increasing to a peak in August in 1938 and 1939, and in July in 1940, and then it dropped off abruptly, with only a few cases through November. All cases were centered in the farming and irrigated areas in the central and western portions of the county. None were reported from the mountains or the eastern desert districts. Treatment during the acute and following stages of the disease was entirely nonspecific. For severe convulsions a variety of sedatives were used. During the comatose state parenteral fluids and gavage feedings were administered as required. Small transfusions and intramuscular injections of blood were given routinely. Physical therapy or casts were used for spasticity or weakness of the extremities. A periodic check of every patient followed discharge from the hospital. Recovery was apparently normal in all of them. Since 97 patients with encephalitis in Kern County during the last three years have given positive neutralization reactions against the western equine virus the evidence suggests that a permanent endemic area exists unless control measures are instituted.

Hypochromic Anemia Terminating in Pernicious Anemia.—Miller and Dameshek cite 2 cases of "primary" or "idiopathic" hypochromic iron deficiency anemia which terminated in pernicious anemia. In the first patient, the Plummer-Vinson syndrome was present and the response to iron was good; typical pernicious anemia that responded to liver extract developed several years later. In the other patient, presenting an apparent typical primary hypochromic anemia, pernicious anemia developed after iron therapy. In this patient apparently

both iron deficiency and liver extract deficiency were simultaneously present and the iron therapy "unmasked" the underlying macrocytic anemia. Constitutional atrophic gastritis with gastric achlorhydria seemed to be present in the first patient. During a period of emotional stress, dysphagia appeared, and because of it a diet deficient in foods containing iron was taken and a chronic iron deficiency appeared. A few years later, probably as the result of functional or organic involvement of the pylorus, the intrinsic factor probably became greatly diminished and pernicious anemia resulted. Evidence in the literature seems to indicate that some persons possess a constitutional predisposition to gastric achlorhydria. This is often familial. During the stage of simple achlorhydria, hypochromic anemia may result, especially if another factor, such as dysphagia, inadequate diet, intestinal malabsorption or hemorrhage, is present. Occasionally the intrinsic factor of Castle may become seriously diminished and pernicious anemia result.

Development of Bronchiectasis.—Ogilvie discusses the natural development of bronchiectasis, in textbook style, under the headings of pathogenesis, etiology, clinical features, roentgenologic aspects, classification and prognosis. He presents an analysis of the condition in 68 patients whom he encountered during the last few years. The lobes of 28 were examined. A classification which recognizes congenital cystic disease of the lung and atelectatic and bronchogenic types of acquired bronchiectasis is suggested. The conclusion is reached that bronchial dilatation may be temporary or permanent. The first is always due to pulmonary collapse and the second is the result of the interaction of many factors, the most important of which is infection of the bronchial wall. The pathogenic factors in bronchiectasis fall under two heads: defects in the bronchial wall and excessive strain and stress to which the wall may be subjected. No conclusive evidence of the existence of congenital bronchiectasis, apart from congenital cystic disease of the lung, has been found as yet. An accurate history and careful physical examination are of utmost importance in the diagnosis of bronchiectasis, as in but few cases have physical signs been absent. The causes of death are classified into three groups: (1) local exacerbation or spread of infection within the lungs or the thoracic cavity, (2) direct complications of associated conditions and intercurrent disease and (3) dissemination of infection via the blood stream and the late results of chronic sepsis.

Acacia for Nephrotic Syndrome.—Goudsmit and his collaborators studied the chloride excretion of 4 nephrotic patients treated with acacia and 1 treated by a dietary regimen and potassium nitrate but no acacia. The major deficiency of renal excretion in the syndrome is in the elimination of sodium chloride and water. After injection of acacia usually considerably more water and sodium chloride were excreted in the urine. This increased excretion brought about a reversal of conditions which was significant and beneficial in comparison to untreated patients. Increases in the volume of the circulating blood or changes of colloid osmotic pressure appear to account for this change in renal function. Potassium salts, particularly potassium nitrate, also increase the amount of water and sodium chloride excreted. Acacia and potassium nitrate seem to remove the fluid of edema from a large percentage of adult patients with the nephrotic type of edema. The mechanism by which acacia increases this excretion is as yet unexplained. An analogous effect might be responsible for the diuretic effect.

Pulmonary Vascular Sclerosis.—Brill and Krygier report the twentieth case of primary pulmonary vascular sclerosis which fulfils Brenner's requirements: significant hypertrophy of only the right ventricle and the absence of any factors commonly believed to cause secondary pulmonary vascular sclerosis, pulmonary hypertension or strain of the right side of the heart. In their case the principal clinical manifestation was severe strain of the right side of the heart resulting in death. Pathologically definite isolated cor pulmonale was present, and the only lesion which might have been related to the fatal cor pulmonale was extensive sclerosis and occlusion of the pulmonary vascular tree. Clinically or pathologically only slight evidence of congestive heart failure was observed. More than a year prior to death the patient, while yet not 20, began to suffer from attacks of precordial pain. Sometimes the pain was

"not radiating," and the attacks were often associated with cyanosis. This is similar to the "hypercyanotic angina" which has been described, especially by the older writers on so-called Ayerza's disease, as occurring occasionally in severe chronic cor pulmonale. Although the coronary vessels were patent and free of sclerosis it appears probable that the sudden death and the earlier attacks of anginal pain were due to acute coronary insufficiency owing to the greatly diminished volume of blood delivered to the left ventricle. Theories concerning the cause and the pathogenesis are discussed, and especial reference is made to the possibility of an essential pulmonary hypertension being related to strain of the right side of the heart similar to that of essential systemic hypertension on the left side of the heart.

Effect of Acute Blood Loss on Normal Subjects.—Ebert and his collaborators determined the effect that the removal of 760 to 1,220 cc. of blood (15.5 to 19.7 per cent of the total blood volume) had on 6 professional blood donors. The blood was drawn in six to thirteen minutes. Collapse, characterized by weakness, nausea, blurred vision, pallor, sweating and fall in arterial pressure, developed in 5 of the 6 subjects. Before the onset of collapse the heart rate increased from 14 to 30 beats per minute above the basal level, but at its height the heart rate ranged from 36 to 40 beats per minute. The plasma volume began to increase immediately after hemorrhage and continued to do so for the next forty-eight to seventy-two hours, at the end of which it was approximately equal to that before hemorrhage plus the volume of erythrocytes withdrawn. During the first two hours after venesection the plasma volume was increased by protein-poor fluid decreasing the serum protein concentration. Thereafter, fluid and protein were added to the plasma and the serum protein remained unchanged, but the total circulating protein increased. Loss of blood acted as a physiologic stimulus for the production of normal protein, and the addition of new protein did not change the proportion of albumin and the various globulin fractions. The blood volume after hemorrhage was not restored to normal until new plasma protein was added to the circulation. Hematocrit readings accurately reflected the direction of a change in plasma volume.

Lipid Nephrosis.—Gilbert followed a typical case of lipid nephrosis for four years and then finally at necropsy. Nephritis with associated uremia developed terminally, and the anatomic changes characteristic of chronic glomerulonephritis were revealed at necropsy. During the four years the patient, a white child 5 years of age at death, was hospitalized thirteen times. On the final admission the clinical picture had changed to such an extent that the diagnosis of lipid nephrosis was no longer tenable, as all the typical signs and symptoms of chronic glomerulonephritis were present. The study supports the thesis that lipid nephrosis and chronic glomerulonephritis are not separate and distinct anatomic entities but merely different manifestations or phases of the same general pathologic process, that is, progressive failure of renal function.

Feasibility of Present Quarantine Methods.—Hoyne states that the usual quarantine methods have failed and that the only foolproof method for suppressing contagious diseases is immunization. Vaccination against smallpox is the outstanding example in this field of endeavor. The value of diphtheria immunization closely follows that of vaccination against smallpox. There was no noticeable suppression of diphtheria until active immunization was introduced. The control of typhoid is another striking example of the value of active immunization. Provisions for the prevention of tetanus, scarlet fever and whooping cough may in time join the ranks. Placarding of the home of the patient with measles is of no scientific value and indirectly may do harm in that the dread of the red quarantine

sign and the possible economic hardship that may result often may cause the parents to hesitate to call a physician when medical attention is most needed. Scarlet fever has not been suppressed by present quarantine measures. Unlike measles, it does not occur in frequent waves of high and low incidence but maintains a comparatively even yearly prevalence. An explanation for this is probably the constant presence of scarlet fever carriers. This is true with respect to immune carriers, and it must occur also to an extensive degree among convalescent carriers arbitrarily quarantined in accordance with public health regulations. From the standpoint of control, it is doubtful that quarantining for poliomyelitis, whooping cough or chickenpox really accomplishes any good. Sometimes rules of quarantine are applied without knowing whether quarantine does any actual good. The author states that these remarks are not intended to belittle proper isolation of patients with communicable diseases. And, as it is neither possible nor feasible to undertake the hospitalization of all patients with contagious disease, proper isolation measures at home will be more readily carried out if the restrictions placed about the family are reasonable. The contagious disease patient should be segregated for the duration of his infectivity. Perhaps in the future contagious disease hospitals will be used primarily only for patients who are so severely ill that hospital care is required and for patients whose contagious disease demands strict quarantine. With these exceptions all other patients with the common contagious diseases may perhaps be isolated in their homes without danger to the community at large and without emblazoned signs proclaiming their misfortune. However, neither quarantine nor isolation but immunization and vaccination will suppress contagious diseases.

Diverse Etiology of Epidemic Influenza.—Lennette and his associates present evidence which shows that acute phase serums were usually obtained between the first and fourth day after onset from patients who provided throat washings and from numerous other patients in each epidemic. Convalescent serums were obtained from the same patients between two and three weeks later. Throat washings were obtained during the first few days of illness from patients with representative and clinically typical influenza. The presence of influenza A or B virus in a throat washing was determined by inoculation of ferrets or Syrian hamsters. The animals' clinical course was

followed carefully. Ten to fourteen days after inoculation they were bled from the heart, and the serum so obtained was run in neutralization tests against approximately thirty 50 per cent mortality doses of influenza A or B virus. Neutralization and complement fixation tests with influenza A virus were carried out with acute phase and convalescent serums obtained from a number of representative cases in each of fifteen outbreaks occurring in six states in 1940 and 1941. In all but three of the outbreaks the evidence indicated that influenza A virus was causally related to more than 50 per cent of the cases studied. On the other hand, evidence that influenza B virus had caused infections was obtained in only 6 cases, in 4 of which there was also evidence of infection by influenza A virus. The many cases in which indication of infection by either virus was not obtained are striking, particularly as these cases were clinically indistinguishable from those in which no difficulty was encountered in establishing an etiologic diagnosis and they occurred simultaneously with the others in each outbreak. It is suggested that these cases (30 per cent of all cases studied) resulted from infection by an agent or agents as yet unknown but distinct from either influenza A or B virus. In these cases no increase in antibodies against either of the two known influenza viruses was demonstrable during convalescence, and throat washings from them, when inoculated into ferrets or hamsters, did not produce antibodies against either virus. On the basis of these completely negative data it seems logical to suggest that there exists at least one additional infectious agent, antigenically distinct from either influenza virus, capable of causing clinical influenza. Since even in single institutional outbreaks of influenza A, influenza B and influenza of unknown cause sometimes occurred simultaneously, it is suggested that epidemics of influenza may frequently have diverse causes. The fact that in a few cases a specific antibody response to both viruses was demonstrated suggests that simultaneous or almost simultaneous infection by the two agents occurred in these cases. Hereafter the finding that some cases in an influenza epidemic resulted from a certain virus will not be adequate evidence that the whole or the major part of the epidemic was due to the one virus, unless of course all the cases are adequately studied.

Total Thyroidectomy for Heart Failure: Unusual Case. W. R. Trotter and K. C. Eden.—p. 200.

Tricuspid Stenosis.—Cooke and White studied 30 cases of stenosis of the tricuspid valve proved post mortem and 12 cases observed during life. In 3 of the 12 the diagnosis was confirmed by necropsy; in the other 9 patients, who are still alive, the disease almost certainly has been correctly diagnosed. The 30 cases were encountered among 4,300 in which necropsy was done, including 217 cases of rheumatic heart disease, in 47 of which the tricuspid valve was involved. In 17 of these the disease was probably of no clinical significance. Twenty-one patients were male and 21 female in the combined group of 33 patients on whom necropsy was done and 9 with clinical disease. The age of the patients at death ranged from 10 to 59 years. Disease of the tricuspid valve may be divided into two types: that occurring in the first three decades of life in patients who die of rheumatic fever and that in older patients in whom the mechanical factors induced by the lesions play an increasingly important part in death. The symptoms in the younger group were almost indistinguishable from those of rheumatic fever, but the course of the older group was characterized by relatively long survival after the appearance of congestive symptoms and signs indicative in most other circulatory disorders of death in the near future. Therefore, owing to the "safety valve" function of the tricuspid valve, older patients may live many years if severe rheumatic fever does not recur. No one sign is pathognomonic of stenosis of the tricuspid valve, but the signs in the order of their importance, especially in combination, are mid-diastolic murmur localized over the tricuspid area, chronic and well defined systolic pulsation of the deep jugular veins, ascites in the absence of pulmonary congestion, enlargement of the heart shadow to the right, deviation of the esophagus to the left, cyanosis and sometimes jaundice, enlargement of the liver with or without pulsation, persistently raised venous pressure and prolonged circulation time of the right side of the heart.

Wertheim's Operation.—Bonney performed 500 Wertheim operations for cervical carcinoma; the follow-up study for 415 covers ten years and that for the others eight years. Most of the patients were between 35 and 60, 36 were more than 60, 34 between 30 and 35 and only 10 less than 30. In only 17 was the growth a pure columnar cell adenocarcinoma; in the rest it was squamous cell, though a tendency to columnar formation was observed in some. The five year cure rate among the 500 women was 40 per cent, but if the 36 who were lost sight of or died of other diseases are deducted the rate was 43 per cent. The incidence of recurrence was 38 per cent, or 41 per cent if those lost sight of and dead of other diseases are deducted. About 65 per cent of the recurrences occurred within two years of the operation. Irradiation or excision of the secondary growth was uniformly unsuccessful. The operative death rate for the 500 patients was 14 per cent, or 70 deaths, death usually occurring within a few hours or days of the operation, in some cases within one or two weeks and in a few after many weeks. Among the 500 women there were 200 whose glands were involved. The five year cure rate for those whose glands were not involved was 53 per cent or 58 per cent if patients lost sight of and dead of other diseases are excluded; whereas for the others the respective percentages were 22 and 23. A similar contrast is exhibited in the operative mortality, respectively 10 and 20 per cent. The relative ten year cure rate for the 415 patients was 31 per cent, or 36 per cent if the 49 lost sight of and dead of other disease are deducted. The author believes that operation has three advantages over radium treatment: 1. It is much easier to conceal from the patient the nature of the disease. 2. Since all that can be done has been done at the operation and recurrence, if it comes, is incurable, subsequent visits are unnecessary and undesirable, as they may arouse suspicion. 3. Operation, unlike irradiation, cures a proportion of patients whose regional glands are cancerous when they present themselves. However, the choice depends on whether the ultimate skill is available.

*Liver Therapy in Diarrhea in Infants. J. E. Virasoro, F. J. Roca and F. Roca.—p. 114.

Liver Therapy in Diarrhea in Infants.—Virasoro and his collaborators report good results in the treatment of benign diarrhea of infants by injections of liver extract, which were given one every other day, up to a total of five to eight injections. The toxic conditions of the patients disappeared early in the course of the treatment. The number of colon bacilli in the feces diminished. The appetite, digestion and general condition of the patients improved. There was a rapid favorable response of the patients to diet and hygiene, with consequent increase of weight and permanent control of the disease. The authors believe that apparently benign diarrhea in infants is due to insufficiency of the liver. The condition results in the development of either chronic or recurrent gastrointestinal and nutritional disorders which may become acute and can be controlled by early administration of liver extract. The authors' article is a preliminary note. Fifteen cases are reported.

*Differential Diagnostic and Prognostic Significance of Repeated Parallel Determinations of Erythrocyte Sedimentation Speed, of Costa's Reaction and of Weltmann's Coagulation Band. O. Lippross and H. Engel.—p. 453.

Depot Insulin in Diabetes Mellitus.—Schweers discusses the retarded action of depot insulins, pointing out that there are three different types. In the first type insulin is combined with protamine and zinc, in the second with the vasoconstrictive hormone of the posterior lobe of the hypophysis, and in the third with substances which retard resorption. Exact comparative determination of the depot action requires hourly blood sugar controls; observations during a period of absolute fasting may lead to erroneous conclusions. Numerous clinical observations convinced the author that hypoglycemia can be avoided by the proper allotment of carbohydrates to the different meals. From three fifths to two thirds of the carbohydrates should be given at the midday meal and small amounts at the morning and evening meals. Acetonuria was especially favorably influenced by the depot insulin containing the hormone of the anterior lobe of the hypophysis. The addition of small quantities of zinc to the insulin to which comparatively large amounts of the hormone of the posterior hypophysis has been added makes it possible to retard the action to such an extent that a reduction of the blood sugar can be observed until the evening or even until the following morning. There was no clinical evidence that the hormone of the anterior lobe of the hypophysis influenced the smooth musculature (intestine, gallbladder, urinary tract) or the cardiovascular system. Elimination of water and sodium chloride was not noticeably affected; in a few cases the addition of the hormone of the posterior hypophysis even seemed to exert a favorable effect on the water and salt retention brought on by the insulin.

Erythrocyte Sedimentation, Costa's and Weltmann's Reactions.—Lippross and Engel cite shortcomings of the sedimentation reaction, as well as of Costa's and Weltmann's reactions. On the basis that the nonspecific reactions of Costa and of Weltmann are at least partly determined by other factors than is the sedimentation speed of the erythrocytes, they made two hundred parallel investigations with these three tests on 53 patients with various disturbances. They were able to show that parallel tests often clarify obscurities of the one or the

other of the reactions and provide a better insight than does the employment of only one of these tests. From the relative deviations of the simultaneously obtained results of all three reactions in the course of such diseases as pulmonary tuberculosis, chronic pneumonia, pulmonary abscess, endocarditis, chronic colitis, diseases of the liver and bile passages, thyrotoxicosis, pernicious anemia, leukemia and neoplasms, it was often possible to draw differential diagnostic and prognostic conclusions. The authors recommend parallel determinations of the three tests.

81:1001-1080 (May 13) 1941

*Studies on Rabies. Maria J. Otten-Van Stockum.—p. 1002.

Studies on Rabies.—Otten-Van Stockum discusses the results in rabies of using a living, formaldehyde treated, fixed virus from monkeys. She also presents experimental studies with formaldehyde treated vaccine and comparative results with phenolized vaccine. She concludes that the mortality from rabies among treated subjects is worthless as a basis for the estimation of the effect of a treatment unless the incubation period is taken into consideration, that is the time that has elapsed between the bite and the onset of the treatment. If account is taken of this, all known methods of treatment fail and only the fixed virus from monkeys, either living or killed by formaldehyde, produces satisfactory results. This is corroborated in animal experiments, provided certain precautions are taken. Experimental investigations carried out over a period of years demonstrated that the efficacy of a fixed virus vaccine is determined by the species of animal used for the preparation of the vaccine as well as by the nature and concentration of the employed rabicidal agent. In using monkey brains (in 10 per cent emulsion) and a 0.15 per cent solution of formaldehyde, with five days' incubation at 37 C. (98.6 F.), a fixed virus vaccine is obtained which proves highly effective in animal experiments as well as in the treatment of human beings.

*Histidinuria, Rapid Method for Detection of Pregnancy. V. Westberg.—p. 180.

Histidinuria, a Rapid Method for Determination of Pregnancy.—Westberg presents a short survey of the chemical properties of histidine and of the various reactions for demonstrating it. He gives particular attention to the methods of Kapeller-Adler (*Wien. klin. Wchnschr.* 47:168 [Feb. 9] 1934; abstr. *THE JOURNAL*, April 14, 1934, p. 1265; *Klin. Wchnschr.* 15:1728 [Nov. 21] 1936; abstr. *THE JOURNAL*, Jan. 23, 1937, p. 341), which he employed in his own studies. Chloroform is quite satisfactory as a means of preserving histidine in the urine. The author's studies were made on specimens of urine from more than 1,000 persons. These included 680 women with intrauterine pregnancy, 11 with extrauterine pregnancy, 61 who had had an abortion, 238 nonpregnant women, 19 men with pulmonary tuberculosis and 3 with Cushing's syndrome. On 14 women in the puerperium serial tests were made. The histidine reaction was negative in 6.34 per cent of the women with normal pregnancy; however, there were only 3.26 per cent of negative reactions among the women who were in the first three months of pregnancy. The histidine reaction was positive for all women with extrauterine pregnancy. The urine of nonpregnant women and of men gave positive reactions in 1.55 per cent of the cases. Histidine is eliminated during the earliest stage of pregnancy; in 7 cases the reaction was already positive before one menstruation had been missed. The serial tests on women in the puerperium disclosed that the secretion of histidine decreases rapidly after normal delivery; the same seems to be true after induced abortion. Comparative mouse, rabbit and histidine tests in 171 cases seemed to indicate that the histidine reaction can compete with the mouse and rabbit tests.

Book Notices

Accidental Injuries: The Medico-Legal Aspects of Workmen's Compensation and Public Liability. By Henry H. Kessler, M.D., Ph.D., F.A.C.S., Medical Director, New Jersey Rehabilitation Clinic, Newark. Second edition. Cloth. Price, \$10. Pp. 803, with 202 illustrations. Philadelphia: Lea & Febiger, 1941.

Ever since workmen's compensation enactments forced on the physician the unenviable job of estimating work capacity or earning power after injury, the medical profession has sought to establish some element of uniformity in disability evaluation. Certainly the first edition of *Accidental Injuries* should be regarded as one of the earliest and longest steps taken to eliminate guesswork and to substitute dependable and rational standards to which all concerned with indemnification for injury might look for authoritative guidance. The solution of these medico-legal problems is about the most elusive in the whole socio-economic field, but books of this kind do hold out some hope that eventually administrative methods can be so reorganized as to allow medical testimony to be offered in personal injury cases with every incentive to be candid and unbiased rather than the exact reverse. Only the full title of the book gives complete insight into the extensive character of its subject matter, since it does treat of the whole field of medicolegal relationships in workmen's compensation and public liability. Relatively little discussion is assigned to diagnosis and treatment as such, although there are a great many comments directed at differentiating between actual as against spurious physical impairment. The present revision does not depart in any considerable degree from the plan of the earlier work. The introductory chapters define and classify the motivation for workmen's compensation and the varying aspects of practical application in our states and territories. Many of the observations in these chapters and in those devoted to the physiology and pathology of trauma are in the author's characteristic philosophic vein. Kessler points out that, although not originally so intended, workmen's compensation contained within it the seed for all subsequent social security legislation—sickness, accident, unemployment and old age insurance. To be sure, it has required the connivance of physician, lawyer, administrator and beneficiary to accomplish this result, both designedly and unwittingly. Every one agrees that such things ought not to be, but the weight of custom and procedure has prevented easy transition to better, fairer and more effective administration. Certainly, one element of reform long overdue is the elimination of prolonged medical controversy in the presence of the claimant, which condition in certain jurisdictions is already being partially corrected through reliance on experienced medical advisory personnel.

The chapters discussing disability in relation to specific or anatomic parts or regions and in relation to the occupational diseases likewise follow the original method of organization. Dr. Andrew Rados has rewritten the chapter on the eye and has incorporated in full the report of the Committee on Compensation for Eye Injuries of the American Medical Association as the standard method of adjudging visual impairment.

Throughout the book are numerous pertinent citations indicating the present trend of decisions in workmen's compensation administration which are an additional reflection of extensive clinical and medicolegal experience developed through long association with the New Jersey Workmen's Compensation Bureau and the New Jersey Rehabilitation Clinic. Certainly no one who reads this work can escape the clear implication that workmen's compensation does not realize a complete social objective through programs of accident prevention and indemnification alone but through the reestablishment of the disabled worker quickly and competently as a self-sustaining unit in the community.

Medicinal Herbs and Their Cultivation. Ministry of Agriculture and Fisheries, Bulletin No. 121. Paper. Price 6d. Pp. 22. London: His Majesty's Stationery Office, 1941.

The importation into England of crude drugs has been seriously curtailed by the war. This booklet is intended to supply information relating to medicinal plants for which there is an urgent demand and which can be grown in that country. In

the foreword appears a statement that a scheme under theegis of the Ministry of Health has been formulated to increase home grown supplies of digitalis, henbane, belladonna and stramonium. In twenty-two pages the booklet discusses briefly the characteristics, cultivation and harvesting of sixteen cultivated herbs, nine wild herbs and seven so-called oil-containing herbs. While some important drugs are included in these lists, it is difficult to understand why in times of emergency agricultural resources and industry should be devoted to the cultivation of such items as aconite, chamomile, pennyroyal, peppermint, valerian, dandelion, buckthorn, elder flowers, comfrey, coriander, parsley, anise and fennel. Somebody in the Ministry of Agriculture and Fisheries appears to have been badly advised on therapeutics, and it would seem the course of wisdom to concentrate any surplus acreage on the growth of digitalis, belladonna, opium, poppy and stramonium, among others.

The Care of the Aged (Geriatrics). By Malford W. Thewlis, M.D., Attending Specialist, General Medicine, United States Public Health Hospitals, New York City. Third edition. Cloth. Price, \$6. Pp. 579, with 50 illustrations. St. Louis: C. V. Mosby Company, 1941.

Specialization in medicine proceeds at a swift pace. Not only has the human body been subdivided into anatomic regions and disease entities, but in pediatrics and geriatrics we find the development of specialties by segmentation of the life span. The specialty of pediatrics, which may be said to have started somewhere in the vicinity of 1860 through the inspiration of Jacobi, has thus far outstripped geriatrics in importance. Geriatrics, like old Rip Van Winkle, is just beginning to awaken from a long slumber. While the renewal of interest in this subject has been ascribed to the increase in the life span, it is more likely a direct expression of the fact that medicine as a science is growing up and getting older too.

Nascher was the first to write a textbook of geriatrics. His book appeared in 1914. The first edition of this book was published in 1919. The present volume is an extensive rewriting of the second edition, which appeared seventeen years ago. The book, as the name suggests, is a guide for those who are directly concerned with the practical care of the aged. It does not pretend to be a scientific treatise on the fundamental mechanisms of the aging process. Essentially the author has taken the common knowledge of medical science and applied it with uncommon good sense to the understanding and treatment of the manifestations of senescence. It is gratifying to know that many of the recently christened advances in scientific knowledge and therapeutics are recognized in a book devoted to the veneration and preservation of the aged. For instance, the theory of Goldblatt on the etiology of hypertension is included; the sulfonamide drugs up to and including sulfathiazole are employed in the recommended therapeutics; the technic of making cutaneous tests with polysaccharides of pneumococci as well as the newer atropine-like synthetics are discussed.

Throughout the volume one finds the most gratifying examples of balanced judgment and common sense; the section on the treatment of arthritis and the last section of the book, entitled "The Mathematical Angle," are conspicuously so. On the other hand it is a curious thing to find hand in hand with so many excellent presentations other material that is either outmoded or open to serious criticism. For instance, the author refers to pernicious anemia, diabetes, hyperthyroidism and leukemia as diseases of exhaustion. He states that liver extract by mouth is said to be of benefit for amebiasis. Laxatives containing sulfur are recommended as the drug of choice in the treatment of constipation associated with hemorrhoids. The author retains the refuted notion that there is something mysterious about obesity. He says "It is not always a question of overindulgence of food, since reduction in food does not always control obesity." In the treatment of severe diabetes crystalline insulin is recommended "if quick action is required," contrary to the best opinion on the subject. The statement that "High caloric diets cause increased endocrine activity, in particular, a high carbohydrate intake affects the islets and a high protein diet puts a 'strain' on the thyroid gland" is subject to serious question. An outstanding departure from the present day expert consensus is the chapter on fibrositis. The author uses this term to include such conditions as "bursitis, lum-

bago, muscular rheumatism, neuritis, panniculitis, sciatica and myalgia." Among the causes of "fibrositis" the author lists indiscretions in diet and vitamin deficiencies as well as describing a relationship to loss of sodium chloride during vigorous exercise. One gets the impression from the book that alcohol is an unmitigated evil. For instance, "alcohol increases the appetite by dulling the brain; thus distention of the stomach may exist without the patient's being aware of it." One is reminded of the remark ascribed to Dr. Llewellys Barker the elder that a man who takes alcohol regularly below the age of 40 is a fool but the man over 40 who takes none is a bigger fool.

Despite the relatively few faults, the volume will be found decidedly worth while by those who are engaged in the care of the aged. The flaws are in its theoretical and technical fine points, not in the practical information and common sense on which its usefulness will rest.

Physical Therapy for Nurses. By Richard Kovács, M.D., Clinical Professor and Director of Physical Therapy, New York Polyclinic Medical School and Hospital, New York. Second edition. Cloth. Price, \$3.25. Pp. 335, with 99 illustrations. Philadelphia: Lea & Febiger, 1940.

A review of the earlier edition in these columns discussed in suitable detail the merits of a nontechnical exposition which attempted to orient those employed as special aids in the administration of physical therapy. Popular demand for this informative textbook has provided the author with that looked for opportunity to arrange and improve its contents in accordance with accepted trends and progress in the field. This edition therefore is not only enlarged and revised but shows an increasing maturity in presenting the essential knowledge of electrophysics and biophysics suitable for the average nurse as a background to her training in the application of physical measures. The work is essentially a manual for nurses and provides concise evaluation of the nature and physiologic effects of certain physical and mechanical forces for therapeutic purposes. The text embraces the clinical action of heat, light, electricity, hydriatics, massage and exercise, measures which in their therapeutic detail are now recognized to require efficient assistance for their successful execution. That the subject matter has been materially enlarged is indicated by the addition of four new chapters which review the historical background of this discipline and evaluate the benefits and limitations of short wave diathermy, artificial fever therapy and colonic irrigation. Throughout these new chapters and the revised text, the virtue which commends itself foremost is the clarity of diction and the absence of padding. An object example is the compact exposition of the section on exercise, written by Dr. McGuinness, and because perfection has been closely approached throughout this volume, a single flaw that tends to mar this contribution, as a painful anachronism is found in the chapter on the history of physical therapy. It is choppy in style and often lacks that critical balance of statements authenticated by fact. Historians certainly will question the assertion which by innuendo credits the discovery of the physiologic action of the high frequency current to Tesla, when as a matter of fact d'Arsonval is credited with its discovery and first enunciation on Feb. 24, 1891. Nor will the student of this discipline consider its history complete without a review of the work of Franklin and Morton in the field of electrophysics. It is because of the general excellence of this work that the hope is advanced that its next edition will overcome the few loose ends in an otherwise valuable contribution.

Traffic in Opium and Other Dangerous Drugs for the Year Ended December 31, 1940. Report by the Government of the United States of America. U. S. Treasury Department, Bureau of Narcotics. Paper. Price, 25 cents. Pp. 105, with illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

The immigration laws were amended on June 28, 1940 to provide for the deportation of any alien convicted of violation of any narcotic drug or marihuana law in the United States. Drug addiction in this country is steadily decreasing. The number of nonmedical drug addicts known is estimated at not more than one in every three thousand of population, a reduction of at least 66 per cent in the last twenty years. The decrease in the amount of ships reaching this country from

abroad in the last two years, on account of the war, has been a factor in the decrease in the drug traffic. Actual deportations were accomplished during 1940 in only thirty-six instances, as compared with fifty-three deportations in the previous year. Secretary of the Treasury Henry Morganthau Jr. had the foresight to obtain for the United States a three year supply of crude opium for medical needs before the Mediterranean Sea was closed to shipping on account of the war. From this reserve the United States Treasury Department has also supplied narcotic drugs for the sick and injured of the many other countries whose supplies have been cut off because of the war.

The largest individual seizure of prepared opium occurred in the Philippine Islands and the next in importance in San Francisco, the amounts seized having been 15,670 and 6,879 Gm. respectively. Raw opium is still scarce in the illicit traffic, and in the latter half of the year the price remained rather constant at \$300 for 1 pound bricks. Peddlers often demanded at San Francisco as much as \$2 a grain for prepared opium. The shortage of all drugs of addiction in the illicit traffic was further evidenced by the increasing number of thefts of these drugs from drug stores and drug manufacturers and by the forging of prescriptions. There was an increase, however, in the smuggling of marihuana into the United States by seamen on boats touching Central and South American ports, as well as an increase in the smuggling of marihuana over the Mexican border. Several of the most horrible crimes committed by persons under the influence of marihuana are reviewed in this report.

The shortage of narcotic drugs has caused addicts and pedlers to make additional efforts to divert narcotics from medicinal sources. This fact has also led to a greatly increased consumption of paregoric. The case is cited of a druggist who did a moderate regular business. A check of his records, however, indicated that he had sold over 321 gallons of paregoric in two years. The druggist pleaded guilty to violation of narcotics laws and was sentenced to a year and a day in prison, fined \$25 and placed on probation for five years. A doctor in Oklahoma in less than two years had purchased 19,500 quarter-grain tablets of morphine sulfate, and of these only 1,497 could be accounted for as having been administered by nurses in the hospital with which he was connected. This doctor was convicted and sentenced to three years in prison and fined \$1,000. A doctor in Arkansas engaged in the illicit drug traffic in cooperation with two druggists. In nine months the drug store purchased 38,000 morphine tablets and in the same period the doctor had written prescriptions calling for 31,667 morphine tablets, all of which prescriptions were filled at this drug store. This doctor was sentenced to two years in the penitentiary and will be placed on probation for five years after he gets out. The two druggists also were sentenced to the penitentiary.

Officials of the Bureau of Narcotics delivered addresses on request in all parts of the country in a preventive educational effort to discourage the use of narcotics, particularly marihuana. Too much encouragement should not be taken from the present decrease in smuggling and importation of narcotic drugs, as the war situation readily accounts for much of the decrease. A resumption of the illicit traffic may be expected when shipping becomes more normal and the boundaries between the various countries can be crossed more readily.

Hospitals Under Fire but the Lamp Still Burns. Edited by George C. Curnock. Cloth. Price, 7s. 6d. Pp. 148, with 32 illustrations. London: George Allen & Unwin Ltd., 1941.

This little book does not attempt to give a full account of the bombing of British hospitals. It does, however, reflect to some extent the effects of bombing on institutions which care for women and children as well as for others, and it does reflect also the manner in which the people of London responded to the attacks that were made on them. The book is replete with illustrations and with anecdotes and is supplemented with a list of the heroes and heroines who were recognized with Distinguished Service medals and with other decorations for their heroic activities during the bombing of the hospitals. Obviously, unless one has been in immediate contact with such hazards it is almost impossible to appreciate the serious conditions that eventuate.

LONG-STANDING SYPHILITIC INFECTION

To the Editor:—An obese Negro woman aged 35 complained of backache with radiation down the outer portion of the right leg and aching pain in the knees. General physical examination showed no abnormalities other than obesity and Argyll Robertson pupils. Tests of blood specimens taken at this time gave the following results: Kahn reaction, positive; Wassermann reaction, anticomplementary. Blood specimens sent to two other laboratories also showed a positive serologic reaction. Spinal puncture was attempted, but I was unable to reach the subdural space with the longest needle available, so that data on the spinal fluid are lacking. Roentgenograms of the lumbar portion of the spine reveal arthritic changes, and the backache complained of is not typical of tabes dorsalis. The patient states that eight years ago, at the time of a laparotomy, she was told that her blood was "O. K." She has never had treatment for syphilis, and there is no history of primary or of secondary lesions. I am unable to find any open lesions now. She is employed as maid and governess in care of two children and was so employed for two years before consulting me. Will you kindly advise me on the following points: 1. What is my obligation as to informing her employer of her condition? The patient herself has told the family that she must take treatments for impurities of the blood. 2. Will you kindly outline a suggested plan of treatment? Intravenous therapy will be difficult if not impossible because of the obesity.

M.D., Illinois.

ANSWER.—1. Although this patient's blood is said to have been normal eight years ago, the presence of Argyll Robertson pupils is a strong indication that the syphilitic infection is of long standing and therefore noninfectious. Under these circumstances the inquirer has no obligation to inform the patient's employer of the diagnosis, and to do so would probably be most unwise because of the possibility of creating syphilophobia in the employer's family.

2. A plan of treatment is difficult to outline without knowledge of the condition of the spinal fluid. In spite of the failure to obtain the spinal fluid on a first attempt, another effort should be made. Obesity is not an adequate reason for failure to secure spinal fluid, since extra long needles for lumbar puncture are available. If tests of the spinal fluid suggest that the patient has parenchymatous neurosyphilis (i. e. if the paretic formula is present) it would probably be desirable, in view of the potential difficulty of administering intravenous treatment, to initiate antisyphilitic treatment with quartan malaria. The quartan strain is suggested because a high proportion of Negroes are immune to tertian malaria. If, on the other hand, the spinal fluid shows only minimal or moderate abnormalities, it is suggested, in view of the difficulty of intravenous treatment, that six months to a year of treatment be initiated with courses of biweekly intramuscular injections of bismarsen (twenty to the course, dose 0.2 Gm.) alternated with courses of ten to twelve weekly intramuscular injections, each 0.2 Gm., of bismuth subsalicylate. At the end of six months to a year of this sort of treatment the spinal fluid should be reexamined and further treatment based on the results.

The chemotherapy suggested is also satisfactory as follow-up treatment for fever therapy with quartan malaria, should the latter prove necessary.

ESTRADIOL DOSAGE

To the Editor:—The Journal for March 22 contained an article by E. L. Sevringhaus on the value of estradiol as compared to similar substances. Does 600 biologic units represent an average dose? How often can that be given to women weighing 115-140 pounds (52-63.5 Kg.) whose sole symptoms are repeated flushings, say twelve in the twenty-four hours? Mild attacks of vertigo at infrequent intervals seem to be associated.

William T. Clarke, M.D., Los Angeles.

ANSWER.—The most potent tablet of estradiol for oral use contains 0.5 mg. and is labeled as giving 600 active biologic units. The milligram equivalent of this number of biologic units has varied in the past, but recently this figure apparently has represented a stable relationship. It should be realized that bioassays of estrogens vary considerably in the hands of different investigators or laboratories. The maximum tolerated dose of this material has never been determined or reported, but the use of 8 tablets daily, given 2 at a dose, is well known to be tolerated as well as useful in certain cases. Doses as low as 50 active biologic units have been employed but seem of little clinical value. The actual dosage for a given patient must be determined by trial as with many other estrogens.

INTRACTABLE PAIN ABOVE SYMPHYSIS PUBIS AFTER HYSTERECTOMY

To the Editor:—A white woman aged 27 had a hysterectomy some twenty-one months ago because of chronic pelvic inflammatory disease. Since that time she has gone to bed and refused to get up and walk, stating that the pain she suffers when on her feet is unbearable. The pain is about 1½ inches above the symphysis pubis, not in the skin or muscle, but it seems deeper. She says that the area of pain is about the size of the palm of one's hand and is constant and burning in character and not referred. I am of the opinion that she has a psychoneurosis but am convinced that she will never get up and walk unless this area is desensitized, for she has a definite phobia concerning it. Is there any method of nerve section or block that would be permanent and still not be too destructive? Please give me what information you can.

John T. Mosley, M.D., Winfield, La.

ANSWER.—There appears to be a psychoneurotic element in the pain of which this patient complains, but everything possible should be done to rule out an organic basis. Since the pain is deep rather than superficial, it is worth while to inject the sympathetic nerves around the cervix. This is a chemical sympathectomy based on the surgical type of pelvic sympathectomy, which has proved to be helpful in cases of dysmenorrhea. The technic of injecting the sympathetic nerve plexus around the cervix is as follows:

The patient is placed in the lithotomy position and an intravenous or gas anesthetic given. The cervix is grasped with volsella and retracted to the right side. A lateral retractor placed in the left fornix will expose this area. A long needle attached to a syringe containing 85 per cent alcohol is passed horizontally through the vaginal mucosa alongside the cervix for a distance of 0.5 cm. The retractor is removed. The needle is then passed backward and outward for a distance of about 1.5 cm. at an angle of 45 degrees to both the sagittal and coronal plane to a point about 0.5 cm. from the side of the rectal ampulla. A finger in the rectum guides the needle to the proper place. After the needle reaches this site, it is withdrawn about 0.5 cm. and 1 cc. of the alcohol solution is injected. While this is being done the needle is kept slightly but constantly in motion. The needle is withdrawn entirely and the same procedure is carried out in the other fornix. Not more than 1 cc. of 85 per cent alcohol should be used on each side, because a larger amount may injure the nerve fibers which control bladder function. The alcohol injures the sympathetic nerves and thereby interrupts the sensory pathways.

PHLEBITIS WITH ITCHING AND EXCESSIVE HAIR

To the Editor:—About five months ago a woman aged 68 had phlebitis in the left leg. The occluded vein extended from the mid thigh, curving down and around to the outside and back of the knee. Now the patient complains of an itching skin area. This area is behind and on the outside of the left knee, and the occluded vein goes down to and through this area. A striking feature of this case is that there is a growth of long hair following right over the curving occluded vein. This line of hair extends for about 12 inches exactly following the vein. The rest of the leg and the right leg are entirely devoid of hair. I should like to know if this is at all unusual and what the explanation might be. What treatment could be suggested for the itching, which apparently is due to this condition?

M. E. Monroe, M.D., Hartford, Wis.

ANSWER.—This is an unusual case; in fact, only 1 case of this kind has been found on record. Louste and Levy-Franckel (*Bull. Soc. de dermat. et de syph.* 36:77, 1929) treated a woman aged 44 for a mild psoriasis and a varicosity in the right leg and thigh. She had had a hysterectomy at the age of 33 followed by artificial menopause. The dilated vein was injected three times in three weeks with a solution of sodium salicylate. When she returned over two months later, the vein was partly sclerosed and over it, extending from the lower part of the external surface of the thigh to the apex of Scarpa's triangle, was a narrow band of pigmented skin covered by hair. Other cases in which pigmented bands developed subsequent to chemical thrombosis have been recorded, but none in which hair grew. Louste and Levy-Franckel discuss the possible pathogenesis of the phenomenon and favor the view that it is due to a local dysfunction of the vegetative nervous system. They promised further reports on their projected research but these have not appeared, possibly because they could not reproduce the phenomenon. The condition cited in the query should be photographed, studied as carefully as possible and reported.

The itching can be mitigated by calamine lotion containing 0.5 per cent phenol and glycerin dabbed on as often as needed, or 1 per cent or more of menthol can be used in place of the phenol but not with it, for these two drugs neutralize each other. An alcoholic lotion containing 1 per cent phenol or several per cent of menthol may be more helpful, or solution of coal tar, N. F., may be used in the same manner.

WOOL UNDERCLOTHING FOR INFANTS

To the Editor:—Would you give an opinion about the use of wool for children in this climate (it is damp, the community is situated near the sea and it is cold at night)? I have had a patient tell me that I am "old fashioned and behind the times, indeed," if I consider putting a thin wool (and silk) shirt on a 9 month old baby. She states that no wool is to be used for children nowadays. I have neither read nor heard anything about this recently, and I felt unable to refute the statement. If it is true, I should like to know by whom and how such a conclusion was reached. What would be the harmful effects of the use of wool for babies or older children when they are kept in poorly heated rooms such as are so often found in the average home here? As long as the sun shines no clothing seems needed, but with the rainy season and the foggy, damp night and morning hours, I shall have to be convinced, and my mind is open to conviction.

Laura C. Killen, R.N., Rancho Santa Fe, Calif.

ANSWER.—The clothing of children varies according to the age of the child and the temperature of his surroundings. The underwear may contain a small amount of wool. Generally speaking, in larger towns and cities the houses are sufficiently heated (around 70 F.) in cold weather so that an infant remains comfortably warm indoors without wool in his underclothing. In fact, the infant is often too warm when his underclothing contains wool.

When he goes outdoors, sufficiently heavy overclothing should be worn to meet the temperature. However, for infants living in poorly heated rooms during the rainy season, as described by the inquirer, especially if the room temperature is below 65 F. during the day, some wool in the underclothing would be desirable.

The chief harmful effect of wool is that it occasionally irritates an infant's skin (producing itching and dermatitis). Some infants are allergic to it. Woolen clothing does not withstand boiling as well, and it may be too warm when the house warms up.

ULTRAVIOLET RAYS AND POLIOMYELITIS VIRUS

To the Editor:—A few cases of sporadic poliomyelitis have appeared in the neighborhood. A recent symposium on this subject in *The Journal* stated that oxidizing agents and ultraviolet rays kill the poliomyelitis virus. Would it be feasible to institute gargles of hydrogen peroxide or potassium permanganate for children (a) as palatable preparations and (b) given daily, without injury to the mucosa? Can ultraviolet rays be applied directly to the oral mucosa, say, daily, without injuring it? If so, what is the dose and how long should it be administered?

Henry Rosner, M.D., Brooklyn.

ANSWER.—Oxidizing agents and ultraviolet rays will kill poliomyelitis virus in vitro, but it is highly improbable that such agents could be made to approximate the virus in vivo. It would be useless to give such agents if the virus had entered the human system and had been absorbed via nerves at some point along the gastrointestinal tract between the mouth and the duodenum, and it would be impracticable to treat any one before that time. During epidemics it is conceivable that such agents might be tried in prophylaxis, but at best the effects would be fleeting. Should the virus be swallowed in the interim between applications, the disease might still result. Potassium chlorate, also an oxidizing agent, has been used in this disease, but experimental and clinical studies have demonstrated its uselessness. Ultraviolet rays will kill the virus of poliomyelitis if they strike directly a thin layer of virus suspension, but theoretically they will not penetrate the mucosa deeply enough, nor could they be applied long enough, to kill all the virus that might be present. Human beings cannot be continuously exposed, and since ultraviolet rays can be given only at intervals the virus could be swallowed between therapeutic exposures and the direct beneficial effects of the rays would be questionable.

PREPARATION OF SULFATHIAZOLE FOR APPLICATION TO EYE

To the Editor:—I have been engaged in the practice of the diseases of the eye, ear, nose and throat for fifty-one years and have had a limited experience with chronic lid trouble of various forms. I thought I would try sulfathiazole for this condition but I have not been able to make a solution, as the most of the drug will not dissolve in water. Can you give me any suggestions about the use of this drug in chronic lid troubles and how I can get a perfect solution of this drug that can be used in the eyes without pain or irritation?

Milton T. Jay, M.D., Portland, Ind.

ANSWER.—Successful treatment of any superficial infection by the local application of sulfathiazole (or of other sulfanilamide derivatives which are active in vitro) is dependent on the maintenance of an adequate concentration of the drug at the site of the infection. Since the effect of these drugs is primarily bacteriostatic rather than bactericidal, an adequate concentration must be maintained constantly and for a considerable period

before the infection is eradicated. This is better accomplished in or about the eye by using sulfathiazole in ointment form rather than in liquid solution, because the latter is quickly diluted and carried away by the tears.

The clinical value of using sulfanilamide derivatives locally for various ocular infections has not been clearly established. Sulfanilamide and sulfathiazole ointments appear to be of value in the treatment of infected corneal ulcers and probably of certain types of superficial conjunctivitis, but this form of therapy is probably of little or no value in deeper infections (Guyton, J. S.: Local Use of Sulfanilamide Compounds in the Eye, *Am. J. Ophth.* 24:292 [March] 1941). Little beneficial effect can be expected in marginal blepharitis, because the drug cannot easily reach the depths of the infected sebaceous and sweat glands.

Sulfathiazole is soluble in water or in physiologic solution of sodium chloride only to approximately 0.1 per cent at 37 C. A 5 per cent solution of sulfathiazole which is only slightly irritating to the eye can be obtained by dissolving the drug in a 10 per cent aqueous solution of triethynolamine. A 5 per cent ointment which is almost nonirritating to the eye can be prepared by mixing exceptionally fine sulfathiazole powder in a petrolatum-hydrous wool fat base. An even smoother and less irritating ointment can be prepared by dissolving the sulfathiazole in a small amount of triethynolamine before mixing it with the ointment base.

GLASSES FOR TESTING NIGHT BLINDNESS

To the Editor:—Is there on the market any reliable device—such as lenses of graded degrees of darkness—which could be used in testing vision by the Snellen chart or similar charts to reveal night blindness? I am not asking about more complicated testing apparatus, such as is used in refractions and other thorough eye examinations, but rather about a simple pair of glasses that might do in the tests of visual acuity, such as a nurse might give, and would indicate the need of a more adequate examination by an eye specialist.

Theodore M. Frank, M.D., Texas City, Texas.

ANSWER.—The series of Tscherning's photometric glasses made in Copenhagen is designed for this purpose. These have a light-proof velvet case and cells in which glasses of an absorption varying in logarithmic degrees are placed. After wearing the no. 8 glasses for ten minutes a normal person can see the bars of a window through them, while a person with night blindness will be unable to do so. Glasses of another number are such that the 20/200 letter of Snellen's chart can be read through them by the normal person after ten minutes' adaptation. Such tests are rather crude and would probably screen out only cases of rather severe night blindness. It is doubted that tests with these glasses would reveal night blindness of mild degree. As far as is known, similar graded lenses are not made in America, but a series of tests on the Snellen chart with ordinary welder's goggles padded carefully to exclude light might establish standards which would be useful. A period of at least ten minutes for adaptation with the glasses on would be advisable.

AMINOPHYLLINE AND MENTAL DISTURBANCE

To the Editor:—For two months I have been treating a man of more than 70 who has been suffering from bronchial asthma for decades. All kinds of treatments have been unsuccessful. The only relief in his heavy attacks is accomplished by (besides occasionally necessary narcotics) intravenous injections of 0.48 Gm. of aminophylline in 20 cc. of physiologic solution of sodium chloride. Is there any danger that these daily injections may lead to other, especially mental, disturbances? His wife told me that recently he often talks incoherently and to himself.

Oskar Ury, M.D., San Francisco.

ANSWER.—There is practically no danger that daily injections of aminophylline will lead to mental disturbance or any other injurious effects. The patient's incoherence may be due to vascular changes due to cerebral arteriosclerosis. Since aminophylline is a vasodilator, it is possible that without the use of this drug symptoms of mental disturbance would be even more severe. Since the dose of aminophylline employed by the inquirer is twice the usual dose, it is suggested that a reduction in the dose may produce equally efficient results.

TYPHOID VACCINE AND SULFANILAMIDE-FAST GONORRHEA

To the Editor:—Is there any rationale to the intramuscular use of a mixed typhoid vaccine in cases of sulfanilamide-resistant, uncomplicated acute or chronic gonorrheal urethritis?

M.D., Tennessee.

ANSWER.—A careful search through the recent literature fails to reveal anything concerning the use of typhoid vaccine in the treatment of gonorrhea as far as sulfanilamide-fast gonorrhea is concerned.

THE PHYSIOLOGIC BASIS OF THE NEUROGENIC BLADDER

JOSEPH P. EVANS, M.D.

CINCINNATI

The propriety of presenting yet another paper dealing with the physiology of micturition might well be questioned since the literature on the subject has become so voluminous as to be repetitious. The presentation of significant new data or the pointing out of new problems would be adequate justification. In this instance, however, I shall attempt so to strip the subject of its physiologic and neurologic complexities as to provide a useful working concept of bladder activity which the practitioner can utilize in handling his everyday problems. The authoritative work of Denny-Brown and Robertson¹ and of Langworthy, Kolb and Lewis² may be referred to for detailed presentation and analysis of the experimental and clinical evidence.

There are several basic anatomic and physiologic facts that are a prerequisite to an understanding of the problem. Briefly they are as follows: The bladder is made up of smooth or involuntary musculature. The detrusor muscle, which expels fluid from the bladder, merges insensibly into the musculature of the bladder neck, which forms the internal sphincter. The two muscles—detrusor and sphincter—receive their nerve supply by way of the pelvic nerves, derived from the second and third sacral segments, and their common nerve supply is reflected by the fact that they act in unison, the sphincter relaxing as the detrusor contracts, and vice versa.

Such coordinated activity makes implicit a neural organization. Sensory data on the state of muscle stretch must be carried to the central nervous system, and motor activity must be initiated over the motor pathways. A graphic concept of such activity³ may easily be obtained by a study of the passage of the nerve impulse upward toward the central nervous system from the musculature of the bladder. One may sample in the experimental animal the nervous activity in the sensory fiber by leading its cut end across electrodes connected with the input of an amplifying system which "boosts" the strength of the action current sufficiently that it activates a recording oscillograph (fig. 1). Resting activity shows a rather low rate of discharge over

the nerve fiber, but when the bladder wall is stretched by the addition of fluid the muscle bundles supplied by the nerve fiber in question become stretched, and the stretch is signaled to the central nervous system by an increased rate of discharge up the nerve fiber (fig. 2). Testing the motor fiber in a similar fashion (fig. 5), one finds that the activity therein changes from one that keeps the muscle of the bladder wall at a level of moderate tension to one which resists the addition of an increment of fluid or which takes part in a concerted effort actually to expel all fluid and thereby to evacuate the bladder. A simultaneous increase in the discharge to the internal sphincter apparently inhibits an inherent tone in the internal sphincter and results in its relaxation if the detrusor contraction is a powerful one (fig. 6).

The sensory fibers bear to the sacral cord segments the impulses indicating the state of stretch of the detrusor and sphincter musculature; the motor fibers bear to the bladder and its neck—that is the internal sphincter—the impulses dictating the motor response. These simple anatomic facts are depicted in figure 4. It should be borne in mind that cells of the anterior horn which give rise to the motor fibers belong to the autonomic or parasympathetic system, as would be expected, since they are destined to supply involuntary muscle.

The problem is simplified if one realizes that the bladder is able to function effectively without participation of the external sphincter. The latter structure serves an auxiliary purpose; it is made up of striated or "voluntary" muscle and its central motor connections also lie in the second and third sacral segments, but the cells of the anterior horn lie in that portion of the gray matter which has to do with the somatic—as opposed to the parasympathetic—system, thus making these centers subject to a greater degree to the control of the will.

The external sphincter is at most times kept in a constant state of "tone" or closure by a steady stream of nerve impulses transmitted from these centers downward to the sphincter by way of the pudendal nerves. Relaxation of the sphincter occurs only when these impulses cease to arrive at the muscle; at such times urine can pass by the sphincter, the passage being abruptly cut off when a resumption of the nervous discharge occurs. The activity over the pudendal nerve is well represented in figure 3. Relaxation of the sphincter, accomplished by interruption of the nervous discharge, can be brought about only by a reflex dependent on contraction of the bladder detrusor, but closure of the sphincter—accomplished by a resumption of the nervous discharge—is under direct control of the will (fig. 8).

It is now well recognized that the nervous control of the bladder is not centered in a particular part of the central nervous system; rather supervisory centers are

located at several points. An analogy might be made to the airfighter squadrons of present day warfare, except that the neurologist refers to "levels" of control. The isolated bladder musculature, whose fibers are unable to act in concert, may be likened to the individual air-dromes deprived of all but the most primitive means of communication. The sacral levels whose function it is to coordinate the activity of the bladder musculature by sensory and motor impulses may be compared to the aerial sector control center, to which information filters

Fig. 1.—Arrangement of dissection to test sensory activity in the nerve supply of the bladder.

and from which commands are forwarded. The mid-brain levels which secure a more complete bladder function and aid in coordination with other bodily activities may be likened to the group control station, and the cerebral centers obviously are comparable to fighter command headquarters.

Fig. 2.—Oscillographic record of increased sensory discharge occurring when sudden distention of the bladder is artificially produced.

The lowest level of bladder activity is, then, the bladder which is isolated from its central nervous system connections. This is the type of activity which one may expect when the bladder is separated from the sacral levels of the cord, as in a complete lesion of the

cauda equina, or when there is interruption of the posterior (sensory) root fibers, as in tabes dorsalis, or when there is actual destruction of the conus medullaris—the terminal portion of the spinal cord containing

Fig. 3.—Upper record shows continuous discharge over pudendal nerve which keeps the external sphincter shut. Lower record shows discharge in abeyance, then sudden resumption of activity coincident with contraction of external sphincter.

the sacral segments (fig. 8). In these instances the innervation of the external sphincter is lost, and since the sphincter is then toneless, as are the other skeletal muscles supplied by the same segments, it no longer

Fig. 4.—Relationship of sacral segments to the bladder. Dotted line represents sensory pathway and posterior root ganglion and solid line represents motor pathway. Plus sign indicates positive effect producing contraction of detrusor. Minus sign indicates negative effect resulting in relaxation of sphincter.

functions and offers no resistance to the passage of urine. Neural organization is therefore limited to the pelvic and intramural plexuses, which contain, in a fashion characteristic of the autonomic nervous system, ganglionic clusters possessed of independent activity. Under these circumstances one can expect only a relatively incompetent coordination of bladder muscle

activity, devoid of effective integration—the isolated airdromes of our analogy.

One may now concern oneself with the next higher level of neurologic function—that which involves reflex activity through the sacral cord. It is at this level that one first deals with spinal reflexes. Through the mediation of the cord segments sensory impulses are coordinated and motor activity is regulated. Thus a spinal transection above the sacral level gives rise to what has been termed the spinal cord bladder. If the severance

Fig. 5.—Arrangement of dissection to test motor activity in the nerve supply of the bladder.

is sudden, there occurs a period of "spinal shock" when all nervous activity below the lesion is in abeyance. Under these circumstances the external sphincter is thrown out of function, the detrusor does not contract and no urine is forced past the bladder neck, which either possesses an inherent tone despite the presence of neural shock or, as believed by some authors, offers a moderate mechanical obstruction to the fluid in the absence of detrusor contraction. The bladder distends inertly until the pressure within the distended relaxed viscus rises sufficiently to force fluid past the mildly resisting internal sphincter.

With the recovery from spinal shock, however, there begins to occur the passage of sensory and motor nerve impulses over the neural pathways. These awake the musculature to activity and waves of contraction occur in the bladder wall. With the onset of a strong contraction of the bladder the internal sphincter relaxes, as does the external sphincter in turn, and urination results. As is true of skeletal muscles in lesions of the transverse cord, there develops a "contracture" of the involuntary muscle of the bladder so that in time the bladder becomes of smaller size, and the reduced capacity results, of course, in more frequent voiding. Furthermore, because the cord bladder falls short of complete neural organization, the emptying is not completely efficient and there is often a residual amount of urine. Such a bladder is of course devoid of all conscious representation, so that its activity is carried out on a purely spinal reflex level, without sensory or motor control from the

supraspinal levels of neurologic activity. The bladder situation in this analogy is like that of fighter units under the command of the sector control station, better integrated but only partially efficient.

Extensive studies in lower animals have shown that there are centers in the midbrain which exert an influence over micturition, and when connections with midbrain levels are maintained the micturition mechanism, though still carried out at subconscious levels, is more smoothly coordinated and voiding is done efficiently. In analogy a group control station is now in command and the situation can be dealt with more effectively.

Finally, there are "centers," located in the paracentral lobule (fig. 7), which represent the highest levels of

Fig. 6.—Oscillographic record of increased motor discharge occurring when sudden distention of the bladder is artificially produced.

neural organization for micturition. Destructive or irritative lesions in these regions result in retention or incontinence, and frequently urinary disturbances in persons with cerebral lesions represent difficulties due not to mental disturbance but to direct involvement of nervous control of bladder activity. In analogy, there is here represented the fighter command headquarters.

No reference has been made up to this point of the role of the sympathetic nervous system. There is evidence, sometimes equivocal, that in certain abnormal states section of the presacral nerves, which send fibers to the urinary bladder, facilitates micturition. But the old concept of the parasympathetic system as being the expellant mechanism, opposed by a "holding" mechanism innervated by the sympathetic system, is no longer generally held. It is probably better to recognize the

Fig. 7.—Mesial aspect of hemisphere, showing paracentral lobule. (From Pauchet and Dupret: Pocket Atlas of Anatomy.)

sympathetic supply to the bladder as dealing with activity of the trigon and of the ureter, with vasomotor control and with sexual function (ejaculation). This

rather arbitrary elimination of the sympathetic nervous system from a role in micturition is probably justifiable pending the production of more convincing evidence of its importance, and for the practical purposes at hand it simplifies consideration greatly.

In recapitulation one may descend the various levels of function. Beginning at the highest level one has the fully integrated mechanism of micturition subject to inhibition by the person who can suppress the desire to void for variable periods of time or who can initiate micturition at will. In passing, it would be well to mention that McGraw⁴ points out in a paper on maturation of neural activity in the child that bladder control may be gained for a time and then be lost as other neural mechanisms develop and demand attention and displace the dominance recently gained. Such fluctuation in control may go on for some time. The matter is of practical importance for it suggests a physiologic basis for the sometimes distressing periods of enuresis through which children pass. She suggests that in the normal child control will develop when the neural organization reaches a sufficiently well developed level and that there is little that can be done to hasten this organization.

At the next lower level of function, which may roughly be termed the midbrain level, micturition occurs subconsciously and without the exercise of the will but may still be very well coordinated.

At the spinal level, following the recovery from shock, a fairly well coordinated activity develops in time. The tone of the muscle is increased in typical cases, the capacity of the bladder is smaller than normal and the emptying is generally not complete. Such bladders are influenced by cutaneous stimuli reaching the central nervous system in the isolated segment, and they affect

Then there is the isolated or autonomous bladder that displays an ill coordinated activity which is devoid of spinal reflex implications because of being isolated from the spinal cord.

There are certain practical considerations which I should like to stress:

1. The bladder musculature should never be allowed to stretch unduly. To do so means stretched muscle fibers, which like those of skeletal muscle are then less well able to respond to nervous activity.

2. A stretched bladder wall is more prone to infection. Infection followed by fibrosis leads to impairment of bladder function and interferes with the resumption of motor activity when nervous control is restored.

3. The bladder musculature is subject to and can be benefited by passive exercise just as in the case of skeletal muscle. Such passive exercise is accomplished by the employment of tidal drainage as long used by Hinman and as popularized by the work of Munro.⁵ Tidal drainage is sound bladder physiology.

BLADDER DIFFICULTIES OF TABETIC PATIENTS

WITH SPECIAL REFERENCE TO TREATMENT BY
TRANSURETHRAL RESECTION

JOHN L. EMMETT, M.D.

AND

J. BYRON BEARE, M.D.

Fellow in Urology, Mayo Foundation
ROCHESTER, MINN.

In previous articles one of us¹ has emphasized that in most cases of vesical atony it is extremely difficult and often impossible to state with accuracy whether the vesical dysfunction is a result of primary neurogenic atony, neurogenic atony complicated by obstruction of the vesical neck or myogenic atony secondary to obstruction of the vesical neck. By means of illustrative cases in these previous papers it was shown that even though the most careful cystoscopic, cystometric and neurologic examinations are performed they often fail entirely to supply the correct answer to this diagnostic problem. It was brought out also that the etiologic differentiation of these conditions may be relatively unimportant as far as treatment is concerned.

This subject assumes considerable importance when patients who are suffering from tabes dorsalis are concerned. The classic description of the pathologic changes found in this disease are "chronic inflammation of the posterior spinal ganglia, posterior nerve roots between the ganglia and the spinal cord and to some extent the meninges, degeneration of the columns of Goll and Burdach, primary atrophy of the optic nerve and interruption of the pathway which has to do with the ciliary reflex."² The vesical symptoms initiated by tabes dorsalis are, therefore, those that result from damage to the sensory roots of the sacral nerves which form the sensory component of the reflex arc that serves for micturition.

Fig. 8.—Relationship of sacral segments to the external sphincter. Dotted line represents the sensory pathway and solid line the motor pathway.

the local reflex arc. This fact explains the emptying of the bladder that may be brought about by penile manipulation preceding catheterization, and likewise the inhibition of micturition by cutaneous stimuli derived from areas less directly related to the micturition arc.

Attempts to present a logical anatomic and physiologic reason for the vesical symptoms found in this disease have resulted in various explanations based on theories as well as facts. It is our aim in this paper to avoid theoretical discussion and to confine ourselves to the statement of clinical observations which we feel should be helpful to the physician caring for these unfortunate patients. Nevertheless, in order to present the subject in an intelligible manner it will be necessary to comment briefly on the more common theories which are currently accepted.

Dees and Langworthy³ have shown experimentally that section of the posterior sacral roots in cats results in an enlargement of the lumen of the bladder accompanied by urinary retention and incontinence. They found that some of this vesical distention could be prevented by passively emptying the bladder by manual pressure or by drainage with an indwelling urethral catheter. Jacobson,⁴ working at the Mayo Clinic, has obtained the same results on dogs. The experimental lesions produced by these investigators simulate the clinical lesion of tabes dorsalis.

On reading articles on this subject, it is necessary to distinguish carefully between statements based on fact and statements based on theory. For instance, that the urinary bladder dilates and urinary retention and incontinence occur after interruption of the sensory part of the reflex arc are facts. The explanation as to why this reaction occurs is theory. One theory is that, because the reflex arc is interrupted, the stimulus to initiate micturition does not get through to the motor side of the reflex arc. Also there is no sensation of wanting to urinate and as a result of these factors the bladder becomes distended. The result of distention is a weakening of the muscle fibers of the detrusor and thus a vicious cycle is established. Some workers in the field⁵ suggest that in this condition the external sphincter may become hypertonic and act as an obstruction to the outflow of urine. Sufficient proof of this statement is not available. Also the subject of incontinence in this disease has elicited much speculation and some rather loose statements. In the literature have appeared such statements as "the incontinence is probably a true overflow incontinence in most cases." We must confess that we also shared this opinion until this study was undertaken. We now realize that, although this is true in some cases, many of these patients who are incontinent do not have any residual urine or have only small amounts.

It is only necessary to read the scanty literature on the subject of vesical disturbances in cases of tabes dorsalis to realize that the subject is still one of the mysteries of medicine. The "hands off" policy has been the physician's procedure of choice for these unfortunate patients, and as a group they have not been especially well cared for in the past. More facts and clinical data concerning this condition are needed if a satisfactory solution to this diagnostic and therapeutic problem is ever to be achieved. In an effort to contribute data to this subject, this study was undertaken.

MATERIAL

This study is based on a review of the records in 977 cases in which the diagnosis of tabes dorsalis was made at the Mayo Clinic during the seven year period

³ Dees, J. E., and Langworthy, O. R. An Experimental Study of Bladder Disturbances Analogous to Those of Tabes Dorsalis, *J. Urol* 31: 359-371 (Nov.) 1935.

1934 to 1940 inclusive. Two hundred and five (21 per cent) of the patients were females. Seven hundred and seventy-two (79 per cent) were males. The age of the patient at the time the diagnosis of tabes was first made at the clinic forms the basis of an interesting grouping of the patients (table 1). It will be noticed

TABLE 1.—Age Grouping of 977 Patients Who Had Tabes Dorsalis

Age, Years	Patients	Per Cent
10-19..	2	0.2
20-29..	12	1.2
30-39..	175	17.9
40-49..	365	37.5

that the majority of patients, 670 (69 per cent), were in the age groups from 40 to 59 years. Of the 977 patients afflicted with tabes dorsalis, 419 (42.8 per cent) complained of symptoms referable to the urinary bladder. It is of interest to note that these figures agree fairly closely with the incidence of urinary symptoms in cases of tabes given by Langworthy, Dees and Lewis⁶ in their study of 278 cases of tabes dorsalis. The relative incidence of vesical symptoms of male and female patients is of interest. Of the 205 female tabetic patients, 74 (36 per cent) suffered from symptoms referable to the bladder, whereas 345 (44.7 per cent) of the 772 male tabetic patients complained of vesical symptoms. The remainder of this study will be confined to the 419 cases in which vesical symptoms were present.

ANALYSIS OF DATA ON 419 CASES OF TABES DORSALIS AND URINARY DYSFUNCTION

Vesical Symptoms.—Vesical symptoms are found most commonly among tabetic patients who are from 40 to 59 years of age (table 2). This is of course the age group in which urinary symptoms of obstruction of the vesical neck occur most often among men who do not have tabes dorsalis.

In considering the type of symptoms encountered in these cases, a word of explanation is in order. In many

TABLE 2.—Age by Decades of 419 Patients Who Had Tabes Dorsalis and Symptoms Referable to the Urinary Bladder

Age, Years	Males		Females	
	Number	Per Cent	Number	Per Cent
10-19	1	1.4
20-29	2	2.7
30-39	51	14.9	12	16.2
40-49	118	34.2	33	44.5
50-59	107	31.0	21	28.4
60-69	28	16.8	5	6.8
70-79	9	2.6
Total	345	100	74	100

of these cases the vesical symptoms were of course purely coincidental and were in no way connected with the tabetic condition. As we mentioned previously and shall attempt to demonstrate subsequently, we feel that it is impossible to state with any degree of accuracy just what part the tabetic lesion plays in the vesical dysfunction in any given case. For this reason we have listed all urinary symptoms complained of by these patients. The incidence of the various urinary symp-

⁶ Langworthy, O. R., and Dees, J. E.: The Urinary Bladder in Tabes Dorsalis. *Ann. Surg.* 60: 364-381 (July) 1936.

toms in the 419 cases is given in table 3. It will be observed that the most common symptoms were incontinence, hesitancy, poor stream, nocturia, terminal dribbling, infrequent desire to void and inability of the patient to tell when the bladder was full. As far as the male was concerned, aside from the incontinence and inability to tell when the bladder was full, the symptoms

Frequency	28	14
Nocturia	89	22

were those common to the condition of uncomplicated obstruction of the vesical neck.

Residual Urine.—The entire group of 419 cases were considered from the standpoint of the amount of residual urine present. We regret that our data on this subject are so incomplete. It will be noticed from table 4 that for 45.2 per cent of the male patients and 71.6 per cent of the female patients no determination of residual urine was made. This high percentage is due to the fact that the clinician in the clinic and to a less extent those of us in the urologic section for years have followed the old dictum that instrumentation in such cases should be avoided when possible. From this table it will be noticed that residual urine is much more common among men than among women. It will be noticed also that only 77 male patients were found to have more than 150 cc. of residual urine, and yet 150 male patients (table 3) complained of some form of incontinence. These figures suggest that though a generous portion of the incontinence in this

TABLE 4.—Amount of Residual Urine Among 419 Tabetic Patients Who Had Symptoms Referable to the Urinary Bladder

Total	345	100	74	100

condition could be an overflow type of incontinence certainly not more than 50 per cent could be attributed to this cause.

Incontinence.—The subject of incontinence is interesting and important. Probably no medical term is used more inaccurately. It is used inaccurately to describe cases of urgency or precipitate urination, to describe the constant dribbling of an overflowing bladder (paradoxical incontinence), to describe the occasional involuntary urination during sleep, and so on.

In short, the word "incontinence" is used to describe so many conditions that an explanation should accompany it each time it is used. In this study it has not been an easy matter in some cases to classify accurately the type of incontinence owing to lack of determination of residual urine or inadequate description of the condition in the patient's history. However, a reasonably accurate classification of the types of incontinence found in these cases has been made in table 5. As mentioned before, 150 males and 37 females complained of incontinence. The most common type of incontinence encountered was a very mild type; this usually was described by the patient as "I occasionally lose a few drops of urine before I am aware of it" or "if I forget to empty my bladder at fairly regular intervals I may lose a little urine." Next in frequency of occurrence was continuous leakage. From table 5 it may be seen that, in more than half of the cases of this type of incontinence in which the amount of residual urine was determined, 150 cc. or more was present. This

TABLE 5.—Type of Incontinence and Its Relation to Amount of Residual Urine Present Among 187 Tabetic Patients Who Complained of Urinary Incontinence

Type of Incontinence	Males					Females				
	Total	Residual Urine, Cc				Total	Residual Urine, Cc			
		150 or More	Less Than 150	None	Not Determined		150 or More	Less Than 150	None	Not Determined
Marked incontinence (including so called overflow incontinence)	42	23	5	3	11	13	3	2	2	6
Very mild and occasional incontinence (occasional loss of a few drops of urine)	57	12	17	2	26	14	0	0	0	14
Incontinence only with straining or coughing	2	0	0	0	2	4	0	0	0	4
Urgency to point of incontinence	6	1	0	0	5	4	0	1	0	3
Incontinence only when bladder was allowed to become too full before voiding	5	2	1	0	2	2	0	1	1	0
Nocturnal incontinence only	38	9	4	4	21	0	0	0	0	0
Total	150	47	27	9	67	37	3	4	3	27

indicates that a generous proportion of these patients was probably suffering from a true overflow type of incontinence. Nevertheless, attention must also be called to the fact (table 5) that several of the patients who had pronounced incontinence had little or no residual urine. The probable reasons for the various types of incontinence will be considered subsequently.

Cystoscopic Data.—In most of the older textbooks of urology the "cord bladder" of tabes is described as one in which cystoscopic examination discloses some or all of the following: (1) reduction in expulsive force of the bladder, (2) reduction in sensation (as determined by how much pain the patient experiences during the time the cystoscope is manipulated), (3) relaxation of the vesical neck (as determined by observation only) and (4) trabeculation of the bladder. The trabeculation is described as being of fine caliber in contrast to the coarse trabeculation seen in the presence of urinary retention caused by obstruction of the vesical neck. All physicians who have had considerable cystoscopic experience will agree that all of these conditions are seen in only the minority of such cases, whereas

in most cases only a few are present. When the latter situation is present, it has resulted in a diagnosis such as "atypical cord bladder."

In studying these 419 tabetic patients who had symptoms referable to the urinary bladder, we were disappointed to find that only 129 had been subjected to cystoscopic examination. The reason for this low incidence of cystoscopic examination is of course the old, ever present, fear of the danger of instrumentation to tabetic patients who have "cord bladders." Unfortunately, the data in these cases in which cystoscopic examination was done were not always given in complete form. For this reason we are unable to present definite percentages for the incidence of the so-called typical findings associated with cord bladder. To make the best of the information available, table 6 is presented. It indicates the number of times reduction in sensation and expulsive force, relaxation of the vesical neck, trabeculation of the bladder and obstruction of the vesical neck were indicated on the records of the cystoscopic examination. One of the most interesting revelations in this table is that the size of the trabeculae in the bladders varied greatly. It will be noticed that the sizes of the trabeculae have been graded from 1 to 4.

TABLE 6.—Data Concerning 129 Tabetic Patients Who Were Subjected to Cystoscopic Examination

Observations on Cystoscopic Examination	Incidence		Total
	Among 111 Males	Among 18 Females	
Size of trabeculae			
Grade 1	26	3	29
Grade 2	19	3	22
Grade 3	21	1	22
Grade 4	6	1	7
Expulsive force reduced	47	5	52
Reduction of sensation	34	7	61
Relaxation of vesical neck	50	12	62
Obstruction of vesical neck			
Lobar hypertrophy of prostate	49	0	49
Bars, contracture of vesical neck or carcinoma	10	0	10
Combination of two types	2	0	2
Total	61	0	61

This suggests that the old dictum that fine trabeculae indicate a neurogenic bladder whereas coarse trabeculae indicate obstruction of the vesical neck may be seriously questioned. This table also shows that definite obstruction of the vesical neck was reported in 61 (55 per cent) of the male patients who were subjected to cystoscopic examination. The obstruction in 49 of these 61 cases was caused by definite lobar hypertrophy, in 10 by bars, contractures of the vesical neck or carcinoma and in 2 by various combinations of the two preceding groups.

We were interested to know whether cystoscopic examination in the cases of incontinence would yield information which might help to clarify the situation. We found that cystoscopic examination had been performed in 48 cases in which incontinence had occurred. The cystoscopic findings are given in table 7. There seems to be no significant difference in data from those obtained in the entire group of 129 cases (table 6) except that the incidence of relaxation of the vesical neck in the incontinent group is somewhat higher.

Treatment by Antisymphilitic and Local Measures.—The question is often asked In what proportion of cases of tabes dorsalis will urinary symptoms improve as a result of antisymphilitic treatment? This question can be answered best by referring to the article on tabes

dorsalis published by the Cooperative Clinical Group,⁷ in which a study was made of 985 cases of tabes dorsalis, in all of which treatment with antisymphilitic measures was employed. The only urinary symptom listed in this article was incontinence. It was found that in 24 per cent of these treated patients the incontinence disappeared during treatment, while in an additional 36

TABLE 7.—Data from Cystoscopic Examination Concerning 48 Tabetic Patients Who Had Incontinence

Observations on Cystoscopic Examination	Incidence		Total
	Among 38 Males	Among 10 Females

Bars, contracture of vesical neck or carcinoma	2	0	2
Combination of two types	1	0	1
Total	16	0	16

per cent the condition was improved. This suggests that the urinary symptoms may be expected to improve in a considerable number of cases of tabes dorsalis after antisymphilitic treatment is instituted. It follows, therefore, that in any questionable case antisymphilitic therapy should always be given a fair trial before more radical therapeutic measures are undertaken.

Treatment by Transurethral Resection of the Vesical Neck.—Of the 345 males who had tabes and vesical symptoms, 35 (approximately 10 per cent) were subjected to transurethral prostatic resection. In some of these cases, of course, the urinary retention resulted from a simple obstruction of the vesical neck and the tabes dorsalis was purely a coincidental finding which played no part in the pathologic condition. In the

TABLE 8.—Residual Urine Before Transurethral Resection in 35 Cases of Tabes Dorsalis

Amount of Residual Urine, Cc.	Cases	Per Cent

majority of cases, however, most urologists would have difficulty in deciding whether the vesical dysfunction was the result of primary neurogenic atony, obstruction of the vesical neck with secondary atony or a combination of the two. This is evidenced by the fact that in 19 of the 35 cases diagnoses such as "cord bladder," "probable cord bladder" or "cord bladder associated

7. O'Leary, P. A.; Cole, H. N.; Moore, J. E.; Stokes, J. H.; Wile, U. J.; Parran, Thomas; Vonderlehr, R. A., and U'silton, Lida J.: Cooperative Clinical Studies in the Treatment of Syphilis: Tabes Dorsalis, *Ven. Dis. Inform.* 19: 367-396 (Nov.) 1938.

with obstruction of the vesical neck" were suggested by either the clinician or urologic consultants who saw the patient. For the majority of these patients in years past operation on the vesical neck would have been rejected because of fear of making them incontinent or increasing an already existing incontinence. In most of these cases cystoscopic examination disclosed reduction in expulsive force, reduction in sensation or both. In several cases relaxation of the vesical neck was mentioned in spite of the fact that definite enlargement of the prostatic lobes also was present. Cystometrograms were made in only a few cases; these revealed definite atonicity of the bladder with decrease in intravesical pressure and a marked sensory shift to the right. As stated previously, we have been unable accurately to establish the etiologic factor in vesical atony by means of cystometry. Thirteen of these patients were incontinent. The incontinence of 6 of them was no doubt a true overflow, as 3 had more than 1,000 cc. of residual urine and the other 3 between 500 and 1,000 cc. Five of the remaining patients who were incontinent were found to have between 100 and 500 cc. of residual urine and 2 less than 100 cc.

Total	35	28	1	2	2

The amount of residual urine found in the entire group of 35 cases is shown in table 8, and the age of the patients is given in table 9.

The amount of obstructive tissue present in the vesical neck in these cases was not great (table 10). It will be noticed that in approximately two thirds of the cases 10 Gm. of tissue or less was removed and 5 Gm. or less was removed in 37 per cent. This serves to emphasize the important point previously mentioned by Braasch and Thompson⁸ that minimal amounts of obstruction of the vesical neck in the presence of an atonic bladder may be responsible for a great amount of vesical disability. It follows, therefore, that the vesical neck must be examined very carefully in cases of this disease.

Results of Operation.—The results of operation in these 35 cases were gratifying. Residual urine was eliminated in almost all cases. Of the 13 patients who suffered from incontinence prior to operation, 11 were relieved completely of this distressing condition. The other 2 were considerably helped. None of the patients who were not incontinent before operation were made incontinent by the operation. We are convinced that there is no more danger of incontinence following transurethral resection in cases of *tabes dorsalis* than in other cases. The patients in whom one would be inclined to expect mediocre or poor results would be the 19 patients in whom it was felt that part if not all of the vesical dysfunction was due to the tabetic

condition. This, however, proved not to be the case. In 15 of these 19 cases, excellent results were obtained and in 4 definite improvement occurred. No patients were made worse by the operation.

In the subsequent follow-up of these patients it has been brought to our attention by O'Leary⁹ and his colleagues that the general condition of the patients shows striking improvement as evidenced by gain in weight, decrease of anemia and lassitude, and especially decrease in the frequency and severity of neuritic pains when the vesical dysfunction is corrected and the residual urine eliminated. This is no doubt owing to the fact that the urinary infection can be controlled more efficiently or eliminated entirely.

COMMENT

As far as the subject of incontinence is concerned, it seems to us that this condition in cases of *tabes dorsalis* is chiefly of two general types, (1) overflow from a distended bladder and (2) intermittent involuntary urination or the occasional loss of a small amount of urine before micturition takes place. This urine is lost apparently because there is so much sensory loss that the patient is not aware that micturition is about to begin. It seems analogous to the condition of enuresis that some patients have while sound asleep. As a matter of fact, many tabetic patients complain of only "incontinence" that occurs during sleep.

We have no clinical data that would tend to confirm the theory that increased tone of the external urethral sphincter of tabetic patients may contribute to the urinary retention and difficult micturition. All of the data obtained from this study point to the fact that fibrosis or contracture of the internal (vesical) sphincter or obstruction in this situation produced by the enlargement of the prostate gland is more likely to be responsible. If any obstruction is present, transurethral resection of the vesical neck will yield brilliant results in many cases. As far as we are aware, any local treatment of the external urethral sphincter has been of no benefit in any of these cases. Any tabetic patient who has difficulty in voiding, incontinence (especially of the overflow variety), residual urine and some demonstrable obstruction of the vesical neck has an excellent chance of relief of symptoms by complete transurethral resection.

Any degree of obstruction at the vesical neck of a tabetic patient, no matter how minute, may produce severe vesical disability, whereas the same amount of obstruction may not cause any disability among patients who do not have *tabes*. The reason for this is quite evident. The interruption of the reflex arc which carries the impulses that initiate micturition plus the inability of the patient properly to recognize the presence of vesical distention (the result of involvement of the sensory fibers of the sacral nerves) results in gradual vesical distention which terminates in various degrees of vesical atony. When the atony is extreme and the involvement of the sensory pathways well defined, the desire to void may never be regained by the patient even though all obstruction of the vesical neck is removed. Nevertheless, such a patient can be taught after resection to empty his bladder by abdominal and manual pressure at regular intervals, so that usually the bladder is completely emptied at each voiding. This makes it possible completely to eliminate the urinary infection by use of urinary antiseptics so that the patient is able to live a fairly comfortable life without incontinence or the necessity of routine catheterization.

⁹ O'Leary, P. A. Personal communication to the authors

THE SURGICAL TREATMENT OF THE
AUTONOMOUS NEUROGENIC
BLADDERREED M. NESBIT, M.D.
ANDWILLIAM G. GORDON, M.D.
ANN ARBOR, MICH.

The autonomous neurogenic bladder results from destructive lesions of the cauda equina or conus terminalis. The bladder is totally deprived of its essential innervation by the parasympathetic division of the autonomic nervous system. The detrusor becomes hypertonic, but, because of the destruction of the spinal reflex, all reflex contractions are abolished. Bladder sensation is lost and voluntary sphincteric control is destroyed (fig. 1).

Sharing in the hypertonicity of the detrusor are those circularly arranged fibers at the vesical neck described as the internal sphincter. The hypertonic internal sphincter acts as a definite obstruction, almost exactly analogous to having contracture of a vesical neck superimposed on the entire picture. As a result, urine does not escape from the bladder until the intravesical pressure exceeds the obstruction in the outlet. Since reflex activity of the bladder is lost, voiding is accomplished only by straining or by continuous overflow dribbling incontinence. As time elapses, the obstructive manifestations become more pronounced as the bladder decompensates and increasing amounts of residual urine remain in the bladder. Ultimately, almost complete decompensation of the detrusor may occur with severe damage to the upper urinary tract.

Since nothing can be done about restoring innervation of the bladder surgical treatment is aimed at removing the obstructive factor. If this can be accomplished the patient should carry relatively small amounts of residual urine. By periodic attempts to void with straining he may also avoid to some degree the unpleasant continuous or periodic dribbling, and, in addition, will be spared the sequelae of decompensation of the bladder and damage to the upper tract.

The earlier methods of managing the problem were by permanent suprapubic cystostomy or by intermittent self catheterization. Permanent cystostomy is unsatisfactory because the bladder rapidly becomes greatly contracted and has practically no capacity. Because of the dangers of infection, self catheterization or a permanent indwelling catheter are poorly tolerated.

More recently, surgical treatment has been directed at relieving the obstruction of the internal sphincter by more direct methods; namely, presacral neurectomy or transurethral sphincterotomy.

Presacral neurectomy was based on the premise that the internal sphincter was innervated by thoracolumbar supply carried through the intact presacral nerves and that it became hypertonic owing to imbalance caused by removal of the parasympathetic inhibition. There is really no conclusive evidence that the internal sphincter has any different innervation than the rest of the detrusor muscle, of which it is only a specialized portion. Furthermore, regardless of the innervation concerned,

prolonged hypertonicity of the internal sphincter may cause it to become permanently spastic. Our limited experience with presacral neurectomy in these cases has not been encouraging.

Transurethral sphincterotomy is a more logical procedure since the obstructive lesion resembles contracture of the vesical neck. The results have proved encouraging, especially when operation is performed before secondary atony of the bladder has supervened. It is of importance to have the resection complete, since the expulsive force of the bladder is already inefficient because reflex activity has been abolished. In the two representative cases presented, the first is an example of the result obtained before secondary atony of the bladder has occurred. In the second case, atony of the bladder had occurred but tonicity was restored after a period of drainage after cystostomy.

Fig. 1.—The autonomous neurogenic bladder is caused by any lesion which destroys the conus or cauda equina. The bladder is completely deprived of external innervation and depends entirely on its intrinsic myenteric plexus, whose fibers lie within the bladder wall. The bladder musculature and internal sphincter both are hypertonic. Despite the high intravesical pressure, the tonic sphincter acts as an obstruction. Since reflex activity is abolished, evacuation occurs only when the intravesical pressure exceeds the sphincteric obstruction. Voiding is by dribbling overflow. A high residual urine is present.

REPORT OF CASES

CASE 1.—E. H., a youth aged 18, admitted Nov. 8, 1940, complained chiefly of having to strain to urinate and intermittent dribbling of urine. His parents stated that intermittent dribbling had been present since birth to a moderate degree. The patient had always had to strain to void, which condition has been slowly increasing in the past three years. He had been seen in the University Hospital in May 1927 and the diagnosis of spina bifida, neurogenic bladder and urinary incontinence was established. There had been moderate increase of straining since that time.

The past and the family history were irrelevant.

A general examination was negative except for saddle anesthesia. The patient voided a poor stream with straining.

Laboratory studies gave negative results except for a definite bacillary urinary infection. The residual urine amounted to 520 cc.

Cystometric study revealed a typical autonomous neurogenic bladder. Panendoscopic examination revealed a hypertonic internal sphincter and heavy trabeculation of the bladder.

From the Department of Surgery, University of Michigan Medical School.

Read before the Section on Urology at the Ninety Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

On Jan. 27, 1941 transurethral sphincterotomy was performed, 3 Gm. of tissue being removed. Microscopic examination revealed this to be smooth muscle with only a few prostatic glands (fig. 2).

After the operation the patient voided easily without straining, and the dribbling incontinence was minimal if the patient emptied his bladder periodically. A check-up one month after the operation revealed no residual urine.

CASE 2.—A man aged 35, admitted Dec. 24, 1940, complained chiefly of straining and dribbling incontinence.

As long as he could remember he had strained to void and lately there was dribbling, overflow incontinence. The straining had increased sharply in the past year, and the urinary stream was merely a dribble. The patient could not tell when the bladder was full but had attempted to void periodically at the time dribbling began.

A soft swelling had been present over the lumbosacral region since birth. There had been continuously present a trophic ulcer of the right foot for six years.

The past and the family history were irrelevant.

On physical examination the pertinent conditions were a lumbosacral meningocele with a small draining sinus. Neurologic conditions were diagnostic of myelodysplasia of the lumbar and sacral cord.

Laboratory examinations revealed no abnormality.

Fig. 2 (case 1).—Section of tissue removed by transurethral resection. It consists almost entirely of smooth muscle with only occasional prostatic glands.

Cystometric examination revealed a bladder in which sensation and reflex activity were lost. There was no rise of intravesical pressure until more than 700 cc. of fluid had been introduced, at which time the pressure increased slowly to 15 mm. of mercury at 800 cc. The residual urine was 600 cc. Cystoscopic examination revealed a heavily trabeculated bladder. The internal sphincter was hypertonic and rigid.

The diagnosis made was decompensated autonomous neurogenic bladder with hypertonic internal sphincter producing obstruction.

On December 26 transurethral resection was carried out, 4 Gm. of smooth muscle being removed. The patient voided much more easily after the operation but continued to carry from 200 to 480 cc. of residual urine. After about two months the stream again became poor and extreme straining with almost total retention developed.

Cystometric examination on April 16, 1941 revealed almost total atony of the bladder. On April 18 a suprapubic cystotomy was done; following this the bladder rapidly recovered its tone, and on May 1 a further transurethral resection was carried out. Following this the patient has been voiding more easily, with residual urine averaging 90 cc.

COMMENT

We feel that it is important to recognize and differentiate the decompensated autonomous neurogenic bladder from the atonic bladder of *tabes dorsalis* and from

the decompensated bladder of advanced prostaticism. In the first instance, the pronounced trabeculation of the autonomous bladder, in conjunction with the hypertonic internal sphincter and characteristic neurologic conditions of destruction of the sacral cord, differentiate it from the atonic tabetic bladder. Differentiation of the decompensated autonomous bladder from the atonic bladder of advanced prostaticism is less easy, but the age of the patient, the history of onset and neurologic and cystoscopic examinations make the distinction readily possible.

SUMMARY AND CONCLUSIONS

The autonomous neurogenic bladder results from destructive lesions of the conus terminalis and cauda equina. Since the internal sphincter shares in the hypertonicity of the bladder, it acts as an outlet obstruction. As with any outlet obstruction, bladder decompensation and damage to the upper urinary tract will ultimately result if the condition persists for a sufficiently long time.

Modern treatment of the autonomous neurogenic bladder attempts to relieve the outlet obstruction. Presacral neurectomy has not proved satisfactory in our experience. Transurethral sphincterotomy yields more gratifying results, particularly if undertaken before the bladder has decompensated.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. EVANS, DRs. EMMETT AND BEARE
AND DRs. NESBIT AND GORDON

DR. WILLIAM P. HERBST, Washington, D. C.: The work that Dr. Evans did in recording nerve impulses was done on animals, and while that is suggestive as to what might occur in man I don't feel that we should take it as being identical and interpret the findings in animals and apply them to human beings. His explanation of the function of the bladder is about as simple as any I have heard or can conceive of and certainly should prove as satisfactory a guide to understanding and comprehension of various bladder dysfunctions as anything that we have had presented to us. Dr. Emmett and Dr. Beare have shown a bright spot in handling tabetic bladder patients with incontinence and retention. They have shown that resection is justifiable and not frequently enough resorted to. The work of Nesbit and Gordon demonstrates a sound idea of the handling of the problem of the atonic bladder. Here we have a bladder that can't empty itself on account of neck spasticity and by the simple procedure of removing this bladder neck obstruction one restores the patient to a much better status.

DR. LLOYD G. LEWIS, Baltimore: I agree with Drs. Emmett and Beare about the treatment of the tabetic bladder. For differentiation between the atonic bladders of vesical neck obstruction and of *tabes*, one needs temporarily to disregard bladder capacity and to study reflex activity by systometry. The normal bladder will forcibly contract when the intravesical pressure exceeds 12 mm. of mercury. In the tabetic patient the voiding reflex fails to develop, even when the pressure reaches 30 or 40 mm. of mercury. In the atonic bladder of obstruction there is a definite response to stretch on 12 mm. pressure, which can be seen in a recorded cystometrogram. I agree with Drs. Gordon and Nesbit in their treatment of automatic bladders. Dr. Evans's study of vesical activity by means of the oscillograph adds to our knowledge of reflex activity of the bladder. We are all aware of coordinated reflexes between the external sphincter and the detrusor. During urination, if the external sphincter is contracted voluntarily, relaxation of the detrusor automatically follows. Henle, Kohlrausch and Rosenthal in 1856 adequately described the bladder neck. At Young's suggestion Wesson studied and described the orderly arrangement of detrusor fibers around the vesical orifice. As far as I know there has been no anatomic description of a true internal sphincter. The prostatic musculature or so-called

sphincter medius is the only sympathetically innervated muscle surrounding the urethra. I cannot accept Learmonth's work on the innervation of the vesical orifice musculature. Learmonth observed the orifice from the posterior urethra during stimulation and section of the presacral nerve. I believe he described trigonal action on the shape of the orifice, rather than sphincteric action. How long must we hypothesize an internal sphincter innervated by the sympathetic nervous system? Henle described the longitudinal detrusor fibers which pass through the vesical orifice to insert in the posterior urethra. When they contract forcibly, the vesical orifice is advanced forward.

DR. HERBERT ELLIS LANDES, Chicago: The analysis of a large series of tabetic patients with bladder dysfunction presented by Drs. Emmett and Beare provides material of great clinical interest. They are to be congratulated on the amazing results obtained by bladder neck resection in these cases. Yet it is a little difficult to see why prostatic resection on the dilated internal sphincter should improve the ability to empty the bladder. I gathered from their statistics that a great many of these tabetic patients had some evidence of vesical neck obstruction, however, and that partial paralysis of the bladder resulted in a relatively high degree of obstruction in the presence of slight prostatic enlargement. Since the tabetic and the prostatic patient have about the same age incidence, the association of the two diseases is not infrequent. Dr. Wilkes pointed out in his paper that small amounts of obstruction produce residual urine out of all proportion to the size of the prostate in these cases. In this group one would expect beneficial results by surgery directed to the relief of mechanical obstruction.

DR. FREDERICK C. McLELLAN, New York: The investigation of Dr. Evans concerning bladder physiology is the necessary background for the understanding of abnormal bladder behavior resulting from disease of the central nervous system. He has clarified the so-called "filling" and "emptying" antagonistic function of the sympathetic and parasympathetic nerves and shown that the pelvic nerves contain the necessary pathways to carry on micturition. The sympathetic fibers play little, if any, part. Since bladder activity is controlled by a spinal cord reflex in the sacral region and inhibited or modified by suprasegmental levels, a study of bladder behavior in many respects parallels that of a somatic tendon reflex. Lesions of the suprasegmental levels may result in increased or involuntary bladder contractions, and, on the other hand, interruption of the essential reflex fibers may result in suppression of the reflex with bladder paralysis. Drs. Emmett and Beare have presented a review of tabetic patients with urinary complaints examined at the Mayo Clinic. They have noted that a certain number of patients, in addition to the paralyzed bladder musculature, have an organic obstruction at the bladder outlet and that this further increases the difficulty in evacuating the urine. Although the neck of the bladder in the atonic neurogenic bladder is usually relaxed and funnel shaped and the urethral resistance is lowered, the coincidence of the older age group makes the possibility of prostatic hypertrophy, carcinoma or fibrous contraction of the bladder neck a not uncommon complication. When trans-urethral resection is adequately performed, the function is improved. The papers of Drs. Nesbit and Gordon and Drs. Emmett and Beare are complementary in that they discuss the two types of bladder paralysis associated with interruption of the reflex pathways, complicated by an obstructing factor at the bladder neck. Whereas Emmett and Beare discuss the atonic neurogenic bladder, Nesbit and Gordon discuss the hyper-tonic or autonomous neurogenic bladder. The spastic so-called "internal sphincter" of the latter type is part of the general tonicity of the detrusor but may cause a definite obstruction to the outflow of urine which, without the obstruction, can be evacuated only by increasing the intra-abdominal pressure or by persistent overflow incontinence. Resection of the internal sphincter permits the urine to be forced more completely from the bladder and, with periodic attempts at emptying the bladder, the patient may be kept fairly dry.

DR. IRVING SIMONS, New York: By observing both sensory points and manometric pressures one can study the relation of true somatic hyperreflexia in neurologic diseases to true hyper-

tonia of the detrusor. One can also show that there is usually hyposensitivity in neurogenic hypotonia of the detrusor, often incorrectly termed tabetic cord bladder.

DR. JOSEPH P. EVANS, Cincinnati: I have but little to add except to express my appreciation of the opportunity of joining in this symposium, from which I have learned a great deal. Dr. Herbst has wisely pointed out that some of the work I presented was based on animal experiments and therefore might not be directly applicable to the present problem. I wish that I could join wholeheartedly with Dr. Lewis in relegating the internal sphincter mechanism to the realm of abandoned theory, because by so doing one can still further simplify the concept of bladder activity. The fact that the action currents running to the region of the bladder neck are the same as those running to the fundus would suggest that the entire fundus and so-called internal sphincter or bladder neck act in unison. It may well be that his explanation will prove to be the correct one. I find it difficult, however, to accept mechanical obstruction as the explanation of the retention that develops following transverse lesions of the spinal cord or following destruction of the conus. I do not say that the sympathetic system has nothing to do with bladder activity. Certainly some sensory discharge is carried over the sympathetic pathways, but it is my belief that under the circumstances of normal micturition the sympathetic system does not play an essential role, either motor or sensory.

DR. JOHN L. EMMETT, Rochester, Minn.: I agree with what Dr. Lewis has had to say in regard to the internal vesical sphincter. I believe many such conceptions must be eliminated from our minds before we can proceed in an orderly manner to discuss the physiology of the bladder. I have not been able to distinguish between a primary neurogenic atonic bladder and a secondary myogenic atonic bladder. Dr. Simons and I have had some friendly discussions by letter about this subject, but I am still of the opinion that I could show to Dr. Simons cystometrograms of severely atonic bladders in cases of long-standing obstruction of the vesical neck in which he could not tell whether the atonicity was a result of obstruction or a primary neurogenic lesion. Dr. Landes has asked a pertinent question. He asked why resection of the vesical neck should be performed on a patient in whom the vesical neck already is dilated. This is difficult to answer, but a case in point may somewhat answer the question: Approximately a year ago a man aged 63 came to the clinic for examination and treatment. Twenty years previously, examination at the clinic had disclosed a severe *tabes dorsalis* accompanied by an overflow type of urinary incontinence. The vesical symptoms were his chief reason for seeking medical treatment. A diagnosis of cord bladder was made, and the patient returned home. His next admission to the clinic, twenty years later, was because of complete urinary incontinence associated with foul, odoriferous urine that made it impossible for him to associate with other people, even though he was most careful to keep his rubber urinal clean. Examination disclosed the presence of between 1,500 and 2,000 cc. of residual urine. At cystoscopy the vesical neck was found to be so relaxed that the walls of the prostatic urethra made almost a right angle at the verumontanum. In spite of the relaxation of the vesical neck there was a small but definite enlargement of both lateral lobes of the prostate gland. It was difficult to see why resection of the vesical neck should relieve this patient, but it did. Only 8 Gm. of tissue could be removed, but after the operation the patient was able to empty his bladder completely by straining, using abdominal pressure and employing about four minutes to perform the act of micturition. He was taught to void at regular intervals four times daily. By this regimen he was able to empty his bladder completely, the overflow incontinence was eliminated completely and it was possible to eradicate the urinary infection.

DR. WILLIAM G. GORDON, Ann Arbor, Mich.: I should like to say one more word about the internal sphincter problem. I hope that I haven't implied that I subscribe necessarily to the idea that there is an internal sphincter; but, in the autonomous bladder, that portion of the detrusor behaves as an obstruction. I have used the term somewhat conventionally, but I am inclined to agree with Dr. Lewis in the interpretation that, if it exists at all, it is unimportant except under this particular set of circumstances.

SKELETAL SCLEROSIS IN CHRONIC
SODIUM FLUORIDE POISONING

PAUL C. HODGES, M.D.

OMAR JOHN FAREED, M.D.

GEORGE RUGGY, M.D.

CHICAGO

AND

JACK S. CHUDNOFF, M.D.

DETROIT

It is established that long industrial exposure to cryolite¹ or to crushed phosphate rock containing sodium fluoride as an impurity² eventually causes severe generalized sclerosis of the skeleton, the tendinous attachments of muscles and of other body tissues. It is known also that the enamel of the permanent teeth of children will be mottled in a characteristic manner³ if the children habitually drink water containing 1 part or more per million of fluorine salts such as sodium fluoride during the years in which the enamel of these teeth is being laid down.⁴

Since mottled enamel is cosmetically undesirable, considerable effort has been exerted to avoid the use of contaminated water, but it has been assumed that the use of such water was not followed by deleterious lesions elsewhere in the body. Recently, however, there have been reported from North Africa,⁵ India⁶ and Argentina⁷ cases of radiologically demonstrable skeletal sclerosis in which fluoride-contaminated drinking water appeared to be the only causative factor.

The present paper deals with an unsuccessful attempt to demonstrate skeletal sclerosis in the inhabitants of first one and then another community in central Illinois where the drinking water, drawn from deep wells, is known to be contaminated with fluoride.⁸

There are American communities in which the fluoride content of the public water supply is much greater than 3 parts per million, and throughout the country contamination of food is increasing because of the widespread use of the fruit and vegetable sprays containing sodium fluoride as the active agent and of phosphate fertilizer and stock food in which fluoride occurs as an impurity.⁹ Since skeletal sclerosis presumably is followed by sclerosis of the bone marrow, kidney and other vital tissues, it is desirable that the search for skeletal lesions should be continued.

From the Division of Roentgenology, Department of Medicine, University of Chicago.

KEMPTON STUDY

The first study was conducted at Kempton, Ill., where the fluoride content of the drinking water appears to be variable over a range of from approximately 1.2 parts per million to 3 parts per million. In this community 86 subjects were examined, the ages ranging from 7½ to 71 years, the exposure to fluoride ranging from none to sixty-one years. In all cases a roentgenogram was made of the pelvis and the lower part of the lumbar spine and in some cases of other parts of the skeleton as well, but in no instance did we observe the occurrence of generalized sclerosis.

BUREAU STUDY

The second study was conducted at Bureau, Ill., where the fluoride content of the drinking water is approximately 2.5 parts per million. Thirty-one subjects were examined, the ages ranged from 18 to 78 years and the exposure to fluoride from eighteen to sixty-eight years. Here also there was no instance of generalized skeletal sclerosis.

Roentgen Technic.—Care was exercised to obtain films of good technical quality. The roentgen equipment consisted of a demountable table provided with a Potter grid and a 1.5 kilovolt shockproof roentgen ray tube connected to an oil-immersed step-up transformer without a rectifier. Films were made at 70,000 volts, 10 milliamperes, exposure time ranging from one second to eighteen seconds, depending on the measured thickness of the part, the exact exposure in each case being determined from an empirical curve which had been found to produce good quality roentgenograms of normal subjects. Films were processed for five minutes in standard strength commercial developing solution maintained at a temperature of 65 F., this work being carried on in a portable darkroom.

Interpretation of Roentgenograms.—As the work progressed, the films were examined and a provisional diagnosis was rendered. Subsequently all the films from both communities, together with films of normal subjects made with the field equipment in the field and in Chicago, were submitted to a group made up of radiologists and orthopedic surgeons.

Dental Observations.—The radiologic study at Kempton had been preceded by a survey¹⁰ in which typical mottling of the dental enamel was demonstrated in practically all the subjects who had been exposed to the contaminated drinking water during early childhood, and earlier studies by others¹¹ had shown typical mottling of the dental enamel of school children in Bureau.

CONCLUSION

1. The use of drinking water containing up to 3 parts per million of sodium fluoride apparently does not cause radiologically demonstrable sclerosis of the skeleton even though the water is taken for a long period of time.

2. As an aid in predicting the result of increased fluoride contamination of food, the search for skeletal sclerosis should be continued in American communities in which the fluoride content of the drinking water exceeds 3 parts per million.

HISTORY AND PRESENT STATUS OF
OXYGEN THERAPY AND
RESUSCITATION

RALPH M. TOVELL, M.D.

AND

JOSEPH E. REMLINGER JR., M.D.

Members of the Department of Anesthesia, Hartford Hospital
HARTFORD, CONN.

During the past twenty years there has been a growing appreciation that oxygen therapy and resuscitation are valuable adjuncts in the physician's armamentarium. Although both are in the infancy of their development, their history may be traced through many years. In ancient times air was considered one of the four elements, and the clinical manifestations of many diseases were attributed to it. Early medical writings record the use of various procedures to stimulate respiration, the function of which was thought to be the cooling of the blood. Under such conditions it is little wonder that attempts to revive those apparently dead had a rather variable fate. The earliest and most successful of these methods was mouth to mouth insufflation, an example of which is found in the Bible.¹ Elisha is said to have restored to life the son of a Shulamite woman by breathing into the mouth of the child.

With the dawn of the seventeenth century many changes in medieval practices were effected. In 1628 Harvey² demonstrated the circulation of the blood. Boyle³ in 1666 proved conclusively that the presence of air was essential for life. Four years later Mayow⁴ observed that this same substance was necessary for the conversion of venous into arterial blood. Approximately a hundred years later, Priestley⁵ isolated the "nitro-aërial" substance of Mayow and called it dephlogisticated air. He did not fully realize the significance of his work, and it remained for Lavoisier to demonstrate that the gas was absorbed by the lungs, burned by the tissues and eliminated as carbon dioxide and water.

The discovery of oxygen aroused considerable interest in medical circles, and in 1798 Thomas Beddoes⁶ established his Pneumatic Institute at Clifton, where the gas was used in the treatment of many diseases. As a result of its abuse and misuse, considerable skepticism arose as to its actual therapeutic value, and during the next hundred years the procedures suffered from the unmerited neglect which eventually supervenes when a method is used as a panacea. However, experimental investigation during this period proved fruitful. Paul Bert⁷ explained the effects of high altitude on respiration as due to a reduction in the partial pressure of oxygen. Zuntz, Mosso⁸ and others elaborated on these observations. Araki⁹ and Walter¹⁰ noted the effects of ingestion of acid on blood and respiration. Cooper

pointed out the deleterious effects of cerebral ischemia.¹⁰ Claude Bernard observed the asphyxial properties of carbon monoxide.¹¹

In the meantime, resuscitation claimed the attention of the medical world. The high incidence of drowning in Holland prompted the organization of the Dutch Amsterdam Society in 1767 for the purpose of formulating reliable life-saving methods.¹² The procedures advocated by the Dutch were presented before the Royal Humane Society in England in 1773 by Cogan.¹³ The measures consisted chiefly of the use of heat, blood letting, rectal instillations of tobacco smoke, barrel rolling and mouth to mouth insufflation. Under the auspices of the two societies rules were formulated and the various methods were approved or discarded as experience proved their worth. In 1776 John Hunter¹⁴ recommended insufflation of air by means of bellows, a method previously suggested by Paracelsus in 1530. The procedure became very popular and the apparatus designed by Charles Kyte was readily accepted by the Royal Society.¹⁵ Hunter also suggested that oxygen, discovered only two years previously, might prove more efficacious in resuscitation than common air. With the publication in 1829 of Leroy's work on resuscitation of animals,¹⁶ the use of bellows fell into disrepute. Since then various mechanical devices have been introduced but for the most part have been considered, until recently, less efficient than manual methods. The most notable of the mechanical devices are the ones supplying intermittent negative pressure and those employing positive and negative pressure, both of which have a definite place in modern resuscitation. Manual resuscitation assumed a scientific basis with the advent of Hall,¹⁵ Howard¹⁶ and Silvester.¹⁷ Although clumsy, their methods were efficient and widely used until 1903, when Shafer¹⁸ described the currently popular prone pressure type of artificial respiration. Recently Nielsen¹⁹ added the "arm lift" to the method, making his a combination of the prone pressure and the Silvester procedure.

With the advent of the World War, the success of Haldane,²⁰ Meltzer,²¹ Barcroft, Hunt and Dufton²² in treating pulmonary edema and pneumonia with oxygen reestablished its use. Since then more efficient means of administering this gas have been developed. Clinicians have become more cognizant of the vicious cycle initiated by lack of oxygen, and the recognition and prompt treatment of this condition is considered a matter of paramount importance.

Anoxia, as it is recognized today, may be divided into four classes, namely the anemic, the anoxic, the stagnant and the histotoxic form. In the anemic type the oxygen tension of the blood is normal but the oxygen content is limited, owing to a deficiency or some functional alteration of hemoglobin. This is best represented by the primary anemias. In the anoxic form, the hemoglobin is unsaturated because of a lowered oxygen tension. The associated reduced tension of carbon dioxide aggravates the condition as it tends to alter further the dissociation curve of oxyhemoglobin. It may result from breathing atmospheres containing a reduced content of oxygen at normal pressures or from any condition in which the alveolar ventilation is reduced. Stagnant anoxia is the end result of cardiac or circulatory failure. The oxygen content and the oxygen tension are essentially normal, but the tissues are inadequately supplied because of a retarded blood flow. This is the condition frequently seen in surgical or traumatic shock. Histotoxic anoxia is essentially a condition in which the cells are incapable of utilizing the available oxygen owing to poisoning. Examples are cyanide, alcoholic and carbon monoxide poisoning.

The direct effects of lack of oxygen have been well described by Barcroft,²³ Haldane²⁴ and others through studies made at high altitudes and in closed chambers in which the partial pressure of oxygen was reduced. Slight deficiency results in hyperpnea and an accelerated pulse rate. Moderate want is characterized by headache, nausea, vomiting and visual and respiratory disturbances. In acute deficiency there is delirium, fever, coma and eventually death. If the onset of anoxemia is insidious, the symptoms are often comparable to those of alcoholic intoxication. There is a feeling of well-being or exhilaration. Mental function is impaired. Emotional disturbances and amnesia are common. Ataxia and muscular weakness develop and are followed by an ascending muscular paralysis. The special senses are gradually lost, hearing being apparently the last to disappear. Unconsciousness occurs and death ensues.

The effect on breathing by a specific reduction of the oxygen content of the inspired air varies with the person and the speed of the reduction. In normal persons a reduction of 7 per cent is usually required to produce a noticeable effect. In others a similar reduction may produce a noticeable reaction. Ordinarily, a slight deficiency of oxygen acts as a stimulus to respiration. If continued, the increased breathing washes out an excess of carbon dioxide and lowers the alveolar and arterial tension of carbon dioxide, and there is a tendency toward production of an alkalemia. With the level of carbon dioxide reduced, respiration becomes quiet and remains so until the gradual accumulation of carbon dioxide in the blood acts as a stimulus. The cycle is repeated and breathing becomes periodic. If the anoxia is allowed to progress further, the apneic phase is gradually prolonged and death eventually occurs from fatigue of the respiratory center. When oxygen want is induced slowly, as in mountain climbing, and when sufficient time is allowed, acclimatization may occur. The alveolar and arterial tensions of carbon dioxide are substantially lowered owing to the rapid shallow breathing. In order to compensate for the alkalemia, and in order to maintain a high tension of oxygen, the kidneys excrete the excess base. If asphyxia develops rapidly, as may occur when an inert gas is

breathed, the initial period of hyperpnea is short and unconsciousness ensues quickly, since the tissues have no oxygen reserve to combat the lowered tensions of oxygen and carbon dioxide.

Similar changes occur in the circulating blood. Incipient anoxia produces dilatation of the coronary vessels²⁵ and a transient rise in the cardiac output and in the frequency of the pulse rate. These are merely compensatory mechanisms to insure an adequate supply of oxygen to the tissues by an increased blood flow. As anoxia progresses, the cardiac output gradually fails owing to lack of oxygen and the accumulation of waste products in the tissues. The latter is important as it tends to alter the hydrogen ion concentration of the blood, which in turn affects respiration. Breathing is stimulated by a rise and is depressed by a fall of the hydrogen ion concentration. With the former, the compensatory hyperventilation tends to alter the hydrogen ion concentration toward an alkalemia by eliminating the excess of carbon dioxide and carbonic acid. In the latter instance the reverse is true.

In addition to the circulatory and respiratory effects other functions may be impaired. The urinary output is lowered by moderate anoxia.²⁶ With prolonged want anuria may develop. The emptying time of the stomach is prolonged,²⁷ contractions²⁸ are reduced and gastrointestinal secretions are modified.²⁹ Besides these immediate effects delayed reactions may occur depending on the time and severity of the exposure. The typical nausea, vomiting and depression of mountain sickness may occur eight to twelve hours after exposure. Such experiences were common prior to the use of oxygen in aviation. Barach³⁰ and others have emphasized the dangers concurrent with flying and recommend the use of oxygen when altitudes of ten to twelve thousand feet are attained.

During many illnesses anoxia frequently complicates the course of disease. By having the superimposed anoxia relieved, the patient is definitely benefited. It is frequently on this basis that oxygen therapy is initiated. In pneumonia, the alveoli are filled with exudate and the lung or part of it is converted into a solid airless organ. As a result, diffusion of oxygen from the air is diminished and the vital capacity of the lungs is lowered. In addition, the presence of hyperpyrexia and toxemia increases the metabolic rate. With metabolism accelerated, the demands of the tissues for oxygen are greater. With the requirement for oxygen increased and the supply decreased, a vicious cycle is established. From a study of clinical records, Binger³¹ concluded that there is a definite correlation between anoxemia and mortality in pneumonia. Other observers have confirmed these observations. Early intervention is essential, as lack of cyanosis in the early stages of the pneumonic process does not infer an absence of anoxemia. Stadie³² has pointed out that the saturation of

the blood with oxygen may drop 10 to 15 per cent below normal before cyanosis is perceptible. This is especially true in anemic patients. Evans³³ states that the efficacy of oxygen is practically in direct proportion to the day on which oxygen treatment is started. In the absence of cyanosis, a pulse rate out of proportion to the degree of hyperpyrexia, the presence of a grayish color and rapid shallow respirations are clearly indicative of anoxia.

In the presence of cardiac disease, impaired function ultimately results in defective circulation and pulmonary edema. Decompensation is accompanied by a lowered arterial and venous concentration of oxygen.³⁴ Peters and Barr³⁵ have reported changes in the dissociation curve for carbon dioxide and in the hydrogen ion concentration of the blood in advanced cardiac failure. Siebeck³⁶ has observed unequal pulmonary expansion in cardiac insufficiency, resulting in an imperfect mixture of the gases in the lungs. Barach³⁷ has described several cardiac conditions in which oxygen therapy has been beneficial, namely congestive heart failure due to primary cardiac disease, cardiac insufficiency as a sequel to chronic pulmonary disease, acute coronary thrombosis and coronary arteriosclerosis with chronic cardiac pain. In congestive failure due to primary cardiac disease, the most significant effects following inhalation of oxygen were decrease of cyanosis, relief of dyspnea and orthopnea and a sharp rise in the content of carbon dioxide in the blood. Associated changes are increased concentration of arterial oxygen, decrease in the concentration of lactic acid in the blood and decreased pulmonary ventilation. Oxygen therapy in cardiac insufficiency as a sequel to pulmonary disease yielded similar results. Currently, the pain of coronary thrombosis is thought to be due to myocardial ischemia. Lewis³⁸ has pointed out that pain results when the blood supply of a working muscle is inadequate. Rizer³⁹ in 1928 noted that the pain could be relieved by inhalation of oxygen. Kissin and Rothschild⁴⁰ have induced attacks of anginal pain by lowering the concentration of oxygen in the atmosphere breathed by patients suffering from coronary arteriosclerosis. Levy, Barach and Bruenn⁴¹ have reported decided relief of pain and subjective symptoms in similar patients following administration of oxygen. Patients with chronic cardiac disease such as those showing congenital defects develop a compensatory mechanism early in life and thus do not warrant oxygen therapy unless decompensation or infection supervenes.

An asthmatic attack produces insufficient oxygenation owing to lowered vital capacity, reduced available pulmonary surface for diffusion of gases, increased residual air and increased negative pressure within the thorax.

Oxygen therapy alone has not proved satisfactory because the volume of oxygen able to pass by the obstructed areas is small. When oxygen therapy has been combined with the administration of helium, significant benefits have been obtained. The use of helium is based on the fact that in diffusion through small apertures the mean free path of helium is greater than is that of nitrogen.⁴² Consequently, oxygen and carbon dioxide diffuse more readily through obstructed pulmonary areas in the presence of helium than in nitrogen. By connecting a delivery tube from a tank of helium and oxygen and from a tank of oxygen by means of a Y tube, the administration of these gases through a Boothby-Lovelace-Bulbulian mask is possible. Barach⁴³ recommends the use of mixtures of helium and oxygen under pressure. Roentgenographic studies revealed that the smaller bronchi are further enlarged at the end of expiration if positive pressure is used.

Oxygen is being administered after major surgical procedures more frequently than formerly. Moon states that anoxia is a factor of utmost gravity in the operation of the vicious cycle associated with shock. Boothby, Mayo and Lovelace⁴⁴ advocate the use of oxygen in concentration of 100 per cent in the treatment of surgical shock because there is an increase of 10 to 15 per cent in the concentration of oxygen in the circulating blood. Under basal conditions hyperthyroidism is frequently accompanied by a slight decrease in the concentration of oxygen in the arterial blood. Following thyroidectomy the administration of oxygen is followed by a definite relief of subjective symptoms. Fine and his associates⁴⁵ advocate the use of oxygen in high concentration in the treatment of distention occurring postoperatively on the basis that when pure oxygen is breathed the gradient of diffusion between the nitrogen existing in the tissues and that in the blood increases. Consequently, there is an increased rate of absorption of nitrogen from the tissues into the blood and thence into the air. On this basis the administration of oxygen following encephalography frequently produces a decrease in the severity and duration of the post-encephalographic syndrome. Schwab, Fine and Mixer⁴⁶ advocate the administration of oxygen both during and after the procedure, even when oxygen is used as the visualizing medium.

The question of dosage in oxygen therapy has received considerable attention. It would seem logical that a concentration should be used which is capable of abolishing the existing anoxia. However, experimental work has shown that animals exposed to concentrations of from 70 to 100 per cent for several days develop pulmonary lesions.⁴⁷ Paul Bert⁶ first noticed that if animals breathed pure oxygen at several atmospheres pressure they soon had convulsions and died. In man,

Benke and Shaw demonstrated that the continuous administration of pure oxygen at one atmosphere was capable of producing untoward effects after six hours.⁴⁸ On this basis oxygen was formerly seldom given in concentrations over 60 per cent. Evans,³³ however, pointed out that the use of such concentrations were inefficient and that higher concentrations were warranted. Sayers found that pure oxygen can be administered for ten hours in man and for sixteen hours in animals without apparent harm.⁴⁹ Barach⁴⁹ confirmed these observations and recommended that pure oxygen should not be given for more than twelve hours a day. Recently, Boothby, Mayo and Lovelace⁴⁴ reported the use of oxygen in high concentrations in more than 800 cases without evidence of pulmonary irritation, but they suggest that the duration of treatment should not exceed forty-eight hours.

Currently there are four popular methods of administering oxygen, namely by means of the intranasal catheter, the mask, the tent and the chamber. Use of an intranasal catheter is an effective method provided the oxygen is efficiently humidified. A flow of 5 to 8 liters provides a concentration of 40 to 60 per cent in the inspired air. To prevent excessive irritation of the nasopharynx and to insure an adequate concentration, the catheter must be well lubricated and properly placed. If it is inserted too deeply there is a tendency for the patient to swallow; if withdrawn too far lower concentrations are obtained at equivalent rates of flow. The best results are obtained by anchoring the catheter at the level of the uvula.⁵⁰ If properly controlled, a tent is a satisfactory means for administering oxygen in concentrations up to 60 per cent. To be effective, frequent checks for adequate ventilation, temperature, humidity and concentration of oxygen and carbon dioxide must be made. Unless this is done, the procedure is both costly and dangerous for the patient. In many ways the administration of oxygen in a chamber is ideal. The patient is comfortable and free from the psychologic effect of knowing that he is receiving oxygen. The disadvantages are the initial expenditure and the greater fire hazard. When concentrations above 60 per cent are warranted, administration by means of a mask is the method of choice. The mask is easily applied, few adjustments are necessary and high concentrations may be obtained with a relatively low rate of flow. Either the basal or the oronasal mask may be used. The former seems more desirable from the standpoint of comfort, but the latter is more efficient when oral breathers are encountered.

We have considered oxygen only as a secondary factor complicating the course of a disease. Our ancestors encountered and thought of asphyxia chiefly in terms of drowning and of foreign bodies within the trachea. The development of the gasoline engine, the ever increasing use of coal, oil and gas in industrial and home life, the widespread use of anesthetic agents and the overcrowding of metropolitan areas have added further hazards. In turn, man has responded by obtaining a more thorough knowledge of the principles of resuscitation. Currently, manual resuscitation by the prone pressure method of Schafer and mechanical means by controlled positive and negative pressure are in vogue. There is considerable diversity of opinion as

to which offers the maximum in effectiveness.⁵¹ There are many who advocate manual methods since they are available, easy to apply and, with an inexperienced operator, less apt to be detrimental to the patient. Mechanical means in experienced hands have a great deal to offer, especially when artificial respiration must be maintained over a long period of time.

Of the manual procedure, Schafer's method is preferred in this country. The prone pressure position promotes the clearing of the pharynx and trachea of foreign material, is easy to perform and carries a minimal amount of risk to the patient. Increasing pressure over the lower ribs produces expiration, while expiration depends on the elastic rebound of the compressed parts. A recent operation or a pregnancy contraindicates the use of this procedure, the method of choice under these circumstances being that of Silvester. Physiologically the Nielsen "arm lift," which aids both phases of respiration, should produce the best results. Expiration depends on pressure over the shoulder blades, and inspiration is aided by the operator lifting the patient's arms. This provides a maximal expansion of the chest. As pressure over the shoulder blades may prove harmful, Drinker and Shaw⁵² have suggested the combination of the prone pressure and the Nielsen method if two operators are available. While one applies pressure over the lower ribs, the other lifts the arms as the pressure is released. Mouth to mouth insufflation has many adherents. It permits an exchange of gases under proper conditions as to temperature, content of moisture and carbon dioxide. Waters and Bennett⁵³ state that it is the method to employ first in severe asphyxia. They prefer it to either the Silvester or the Schafer procedure. Satisfactory results may be obtained by administration of oxygen or mixtures of oxygen and carbon dioxide by means of a simple inhalator in conjunction with the prone pressure method.

Mechanical resuscitators are of two types: those employing intermittent positive pressure and those providing alternating positive and negative pressure. In the former expiration depends on the recoil of the distended parts, while in the latter the additional aspirating action due to negative pressure aids expiration. The principle involved in both has aroused considerable controversy. It is well known that excessive intrapulmonary pressure may produce irreparable damage. Positive pressure has been condemned by some because the force necessary for inflation in the presence of atelectasis or obstruction exceeds the upper margin of safety. Polak and Adams in experimental work on dogs have used pressures as high as 8 mm. of mercury without apparent harm.⁵⁴ In man, pressures of from 30 to 40 mm. of mercury are conceded to be safe. Coryllos⁵⁴ advocated the use of pressure, stating that it is the only means whereby successful insufflation with oxygen may be produced when muscular tone is lost. The value of the cupping action due to negative pressure is debatable, some observers holding that it has

a harmful effect on the alveoli and prohibits an adequate exchange of gases during expiration by constricting the smaller bronchi too rapidly. The efficiency of both methods may be enhanced by the use of a well lubricated soft rubber intratracheal catheter to assure a patent airway. Prolonged intubation should be avoided, as it is conducive to tracheitis. If used in conjunction with the application of positive pressure a stomach tube should be passed to prevent gastric distention. When artificial respiration must be maintained over a long period, as in the presence of intercostal paralysis, the efficacy of the Drinker or Emerson respirator is beyond question. If the lungs are collapsed or respiration has not been initiated, the apparatus is of little value.

The patient asphyxiated with carbon monoxide presents a rather complex problem. The affinity of carbon monoxide for hemoglobin is two hundred and ten times that of oxygen.⁵⁵ It combines readily and forms a more stable compound with hemoglobin than does oxygen. Because of its high affinity for hemoglobin even low concentrations in the inspired air are dangerous. The essential features of carbon monoxide poisoning are lowered concentration of oxygen, reduced tension of carbon dioxide, depressed respiration and loss of bodily heat. The most effective physiologic means for breaking down the combination of hemoglobin and carbon monoxide is offered by the mass action of oxygen; the most effective stimulus is carbon dioxide. In mild poisoning, the use of oxygen alone produces good results, as ventilation is adequate and no further stimulus to respiration is needed. In such cases Sayers and Yant⁵⁵ advocate the use of pure oxygen, stating that it is more efficacious than are mixtures of carbon dioxide and oxygen in preventing occurrence of delayed symptoms. As asphyxia progresses, the threshold for stimulation of the respiratory center rises and respiration becomes depressed. The rationale of using carbon dioxide is based on two facts: First, it produces adequate ventilation by its action on the respiratory center; second, it has a desirable effect on hemoglobin, facilitating the release of oxygen to the tissues. Ordinarily, concentrations of 5 to 7 per cent are employed.⁶⁶ A discussion of the value of various drugs as respiratory stimulants in asphyxia is beyond the scope of this paper. At present both experimental and clinical evidence seems to indicate that they are of little value.

The first inspiration of the newborn is essentially a resumption of a function previously established in utero.⁶⁷ Suppression of this function has been attributed to many factors. Eastman⁶⁸ in 1930 reported that the blood of many asphyxiated newborn infants contained a high tension of carbon dioxide and a low content of oxygen. On this basis he suggested that the failure of respiration was due to impairment of the respiratory center from anoxia and not from lack of chemical stimulation. Snyder and Rosenfeld⁶⁹ have shown that mater-

nal anoxemia produces a depression of fetal respiration without the preliminary stimulating effect which occurs in adults. When severe anoxia or narcotization occurs, complete cessation may occur. They also observed that lowering the carbon dioxide tension produced respiratory depression, while raising the tension above normal failed to stimulate breathing. In addition to these factors, it must be remembered that at birth cerebral compression, hemorrhage, mechanical interference with the fetal circulation or incomplete dilatation of the lungs may produce or aggravate an existing anoxemia.

The asphyxiated newborn infant should be handled gently and as little as possible. The mouth and nasopharynx may be cleaned of mucus by postural drainage and aspiration with a catheter. If necessary, the catheter may be inserted into the trachea blindly or under direct vision with a laryngoscope. Warm tubing is advocated, but cold tubing should never be employed, as the baby's heat must be conserved and not dissipated. If aspiration, application of external heat and cutaneous friction fail to stimulate respiration, oxygen should be given immediately by intermittent positive pressure. In some instances mouth to mouth insufflation may be indicated. Once breathing has been initiated, oxygen should be continued until respirations are full and regular. If respiration continues to lag or if pulmonary ventilation is deemed inadequate, the infant should be transferred to an incubator equipped as a chamber for the administration of oxygen.⁶⁰ Wasson,⁶¹ Van Reuss⁶² and Henderson⁶³ have reported that frequently complete expansion of the lungs may not occur for several days. Therefore, continuation of treatment during this period is essential.

COMMENT

A knowledge of the efficacy of the administration of oxygen has been gained through the efforts of many investigators. Regardless of the method employed, ultimate success of treatment with oxygen depends on early intervention. The reserve supply of oxygen within the body is capable of maintaining life for only a few minutes. Once this supply is exhausted, irreparable damage to the central nervous system may occur within a comparatively short time. Delay in instituting artificial respiration or in administering oxygen may result in death or in the production of a deranged mind within a sound body.

ABSTRACT OF DISCUSSION

DR. ALVAN L. BARACH, New York: I am pleased that oxygen therapy is about to be formally introduced as a part of anesthesiology. It seems fitting that the specialty of anesthesia, which includes relief of pain, should extend itself to relief of dyspnea. Oxygen therapy exercises the effect of reducing the volume of breathing in anoxic dyspnea. Its special value is in maintaining a rich oxygen supply to the tissues of the body, primarily to the brain. As the authors point out, the brain is the most sensitive organ to oxygen want. Helium is a light gas, which, when mixed with oxygen, can be breathed through narrow orifices at a pressure approximately one-half that required for the movement of either air or pure oxygen. This fact has been made use of in the treatment of asthma and localized obstruction. It has been pointed out that the viscosity of helium is slightly greater than nitrogen and that, if helium was to pass through a tube that was prolonged so that frictional resistance took place, the function of helium would not be

advantageous. The main use of helium is in respiratory obstruction, in which it has the special physiologic value of lowering the pressure in the chest required for the movement of air in and out of the lungs. Positive pressure is used not only in asthma and in localized obstruction but in edema of the lungs, and this is of special importance at this time, when we are faced with the possibility of war gas poisoning. Edema of the lungs occurs not only as a complication of certain medical and surgical illnesses but also during anesthesia. It has been found that a pressure of 5 or 6 cm. of water, applied to the inside of the lungs by inhaling oxygen through a hood or through a mask, will stop exudation of serum, frequently within a short period. One has to bear in mind that excess pressure will prevent blood from entering into the right heart. But pressures of 5 and 6 cm. of water will in many instances prevent edema of the lungs, and that is something to remember in case one ever comes to a point where irritative gases cause an increased exudation of serum.

DR. FREDERICK A. D. ALEXANDER, Albany, N. Y.: There are some three thousand references in the literature to gas therapy and resuscitation. The authors have picked from this mass of information the most pertinent and the most important. It seems to me that oxygen therapy needs no brief at this time. It is thoroughly established and recognized everywhere. I wonder if we might not to better advantage think more of resuscitation, which, although it is much older than gas therapy, has been more or less taken for granted. More of our efforts, more of our thoughts should be given to resuscitation. As Dr. Barach has suggested, we may need to know a great deal more about resuscitation within the next few months or years. I should like to present a reclassification of the various types of oxygen want. All are familiar with Barcroft's classification of anoxia: anoxic anoxia, anemic anoxia, stagnant anoxia and histotoxic anoxia. The term anoxia is as incorrect as was the term asphyxia generally applied to oxygen want or as was the intermediate term anoxemia. There is no such thing as anoxia in clinical medicine. Any patient who has no oxygen in the blood stream cannot possibly survive. I propose the classification based on the site of the disturbance of the transport of the physiologic gases, with the term "hypoxia" rather than anoxia: atmospheric hypoxia, respiratory, cardio-circulatory, hemic and histotoxic: atmospheric, such as is seen occasionally in anesthesia; respiratory, as in upper respiratory obstruction or at the alveolocapillary membrane or in peripheral respiration insufficiency; cardiocirculatory, in circulatory disturbances where the difficulty is in the heart or in the vessels; hemic, such as we might see with anemia or with the use of the dyes where the hemoglobin has been, temporarily at least, prevented from transporting oxygen.

DR. RALPH T. KNIGHT, Minneapolis: I should like to ask Dr. Barach to amplify one of his statements with regard to the pressure, so that I will understand it more clearly. He showed us that a slight increase in pressure very much increases the passage of either helium-oxygen or oxygen alone through small passageways. If that is true, it seems to me that this increased pressure would also impede the exit from the lungs and would therefore impede ventilation. If we are using a pure oxygen, this would not interfere with the physiology to any extent except that it would reduce the output of carbon dioxide. If we are using helium and oxygen, it occurred to me to wonder whether in such an instance the helium would not accumulate in the lungs to the detriment of the presence of oxygen.

DR. BARACH: Patients with emphysema or asthma during the period of distress manifest a very severe dyspnea, breathing out against partially closed lips. I once had the occasion to ask such a man to open his mouth and breathe, and he swiftly went into an even more violent dyspnea. That was largely responsible for the use of positive pressure in our clinic. Dr. Swenson and I put iodized oil into the bronchi of patients with asthma and then had them breathe naturally and under positive pressure; we showed by x-ray films an increase in the diameter of the bronchi during expiration as a result of this positive pressure reflected backward through the bronchial tree, which tended to keep the bronchi open. There is an increased effort during expiration to exhale the gas against a positive pressure. This, however, is an effort which has peculiar advantages to the

patient not only in keeping his bronchi open but in preventing edema of the lungs. I have mentioned in an article in THE JOURNAL on the use of helium the physiologic advantages of grunting and groaning. If one sees a patient with lobar pneumonia in dyspnea, one is impressed with the enormous positive pressure developed during the expiratory grunt, which we have measured in a tracheotomized subject. It may go as high as 20 mm. of mercury, very often 10 or 15, during expiration. That pressure against the capillary wall prevents oozing of serum. I had the misfortune once to give such a man, who I thought was suffering from severe dyspnea, enough morphine to stop completely his expiratory grunt and witnessed the development of the edema of the lung within a period of three quarters of an hour afterward. The pulmonary ventilation is the same or slightly lower with positive pressure. The tidal air comes in, 500 cc., but it goes out in such a way, owing to the opening of the tracheobronchial tree by pressure, that a more uniform ventilation of the lungs takes place, especially in areas of the lung that may have been closed by partially collapsed alveolar ducts and plugged bronchi.

DR. RALPH M. TOVELL, Hartford, Conn.: I should like to mention the physical principles involved in the administration of helium. I quote Visscher from an article of his entitled "The Physiology of Respiration," published in the November 1940 issue of the *Bulletin of the Minnesota Medical Foundation*: "The use of helium is based on the fact that, in diffusion through small apertures, the mean free path of helium is greater than is that of nitrogen." This is an interesting concept that had been appreciated by Barach.

TUBERCULOSIS CASE FINDING

A PRACTICAL AND SUCCESSFUL PROGRAM FOR NONMETROPOLITAN AREAS

THEODORE L. BLISS, M.D.

Director of Richland County Case-Finding Clinic
AKRON, OHIO

In the literature of tuberculosis case finding there are only a few reports dealing with nonmetropolitan areas. Probably the main reason for this lack is the absence of case-finding programs in most such areas. Yet there is as much need for effective tuberculosis control in nonmetropolitan areas as in areas of highly concentrated population. Hence I present this report on a case-finding clinic in successful operation for five years in a nonmetropolitan county in Ohio. Richland County has a population of approximately 74,000, equally divided between the one urban district of Mansfield and the rural districts.

Late in 1935 Dr. Millard Hanson, then the health commissioner of Richland County, sought and obtained funds from the local tuberculosis association to establish a case-finding clinic. He asked me to take charge of the program. A set of regulations was drawn up which made it an integral and permanent function of the health department and provided for the active participation of the private physicians in the county. These regulations were submitted for approval and passed by the county medical society. The clinic which was established is intended to be a chest disease clinic rather than exclusively a tuberculosis clinic. Private physicians are invited to refer any patient with evidence of a pathologic condition of the chest that otherwise could not be definitely diagnosed, as well as patients in whom they suspect tuberculosis. Thus the clinic is able to aid the physician to solve his problems in diagnosis of diseases of the chest, and at the same time it provides an opportunity for examination of the group of patients known

Read before the Section on Preventive and Industrial Medicine at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

to be the most fertile source of tuberculosis. The clinic is scheduled regularly and provides each patient with a roentgenogram of the chest, pertinent laboratory tests and a physical examination of the chest by the clinic physician. Only patients referred by a physician or by the health commissioner are accepted by the clinic. They are classified as suspects. In order that the patient-physician relation may be maintained, the results of the examinations are mailed to the referring physicians and are not given to the patients.

There is another group of clinic patients, the tuberculosis contacts. The regulations permit the clinic nurse to visit the family of a tuberculous patient to urge the contacts to be examined. This is surely a matter of primary importance. Yet the private physician cannot be held responsible for this job, either because he does not fully appreciate its value or because he is not in a position to carry it out. If the contacts are under 12 years of age they are given a tuberculin test, and only contacts with a positive reaction have roentgenograms made of the chest. Since it is also essential to follow up the contacts, they are asked to return for recheck examinations at varying intervals for varying periods of time determined by the epidemiologic factors in the individual case. When a patient presents evidence justifying a diagnosis of inactive tuberculosis he also returns for periodic recheck examinations. When, however, a patient is found to have active tuberculosis the report to the referring physician includes recommendations for treatment but his further observation is not considered within the province of the case-finding clinic, since according to state law he is entitled to aid from the general tax funds.

The health department provides the services of a nurse exclusively for the clinic. Obviously, the success of the program depends on the cooperation of the physician in private practice, the health commissioner and the tuberculosis association.

In order to measure the results of this case-finding program several criteria have been selected.

1. Is the clinic actually investigating a reasonable percentage of the reported cases of tuberculosis in Richland County? In the first year of the clinic in only 56 per cent of the 48 cases of tuberculosis reported to the health department was diagnosis made in the clinic, while in the fifth year in 93.8 per cent of the 49 reported cases diagnosis was made there.

2. Is the management of the clinic economically sound? This is of fundamental importance and may be measured by the number with tuberculosis found in each hundred patients examined. I shall also consider the percentage with disease of the chest other than tuberculosis, since the clinic is primarily a chest disease clinic. If the incidence of tuberculosis among the patients examined is too high it indicates that the clientele is so highly selected that it does not include a great many of the very persons for whom one is looking, namely all the persons in a given district who have tuberculosis. Conversely, if the incidence of tuberculosis is too low it indicates that the wrong persons are being examined and that the cost per case found is unjustifiably excessive. During the five years of operation of the Richland County clinic 1,270 new patients were examined, 175 (13.7 per cent) of whom had active tuberculosis. Of the 175, 155 had pulmonary tuberculosis. The yield for the five years is too high, although the rate has been decreasing each year since the clinic was founded. This high rate is not an index

of an excessive incidence of tuberculosis in Richland County, since the death rate during the past five years has averaged 24 per hundred thousand. However, it shows that physicians must be encouraged to refer a larger number of patients to the clinic for examination. In addition to the 175 patients with active tuberculosis, 47 were found to have inactive pulmonary tuberculosis and 156 nontuberculous pulmonary disease, making a total of 378 with some kind of pathologic condition of the chest, or an incidence of 29.7 per cent among the 1,270 new patients examined. The nontuberculous pulmonary diseases included bronchitis, nontuberculous pleurisy, pneumonitis, empyema, bronchiectasis, abscess, carcinoma, silicosis and cystic disease.

3. Has there been an increasing percentage of patients whose disease has been diagnosed in an early stage? The tuberculous patient with incipient disease may be considered as probably noninfectious and the patient with moderately advanced disease as possibly infectious, while the patient with far advanced disease is almost certainly infectious. My aspiration is to attain a falling percentage of patients with far advanced disease and a rising percentage with incipient disease. During the five years the percentage with far advanced disease among the patients having pulmonary tuberculosis has decreased from 77 to 43, and the percentage with incipient disease has risen from 13 to 34. This is progress in the right direction.

4. Has it been profitable to examine the contacts? Among the contacts who have tuberculosis, the percentage with incipient disease should be large, even though a relatively small number have tuberculosis. Among both new patients and patients returning for recheck examinations during the five year period, 31 contacts were found to have tuberculosis, of whom 18 (58 per cent) had the disease in its incipient stage. In the group of suspects 144 had tuberculosis, 32 (29 per cent) in the incipient stage. Thus the incidence of incipient tuberculosis is two times greater among the contacts than among the suspects. This is convincing proof of the importance of examining contacts in the attempt to discover the disease in the incipient stage.

5. Has the program stimulated public interest? Since the case-finding program is supported by the sale of Christmas seals, the total annual sales should offer an index to public interest. Each year the sales have increased. In 1940 the per capita sale in Richland County was three times the average for the five years preceding the founding of the clinic, and in 1940 was 60 per cent above the per capita sales in the state, whereas in the five years prior to establishment of the clinic the average per capita sales in Richland County had been only 12 per cent above the average for the state as a whole. Another example of the public's approval of the program is the passage of a tax levy to provide more funds for the treatment of tuberculous patients. The finding of many new patients requiring treatment resulted in increased demands for money from the general tax receipts. In order to meet these needs the county commissioners submitted to the electorate at the 1938 elections a proposed five year 0.5 mill tax levy to be used exclusively for the treatment of tuberculous patients who were legal residents of Richland County. The levy was approved and provides an annual revenue which is five times the average annual appropriation for the treatment of tuberculous patients during the ten years preceding the founding of the clinic.

The following lessons may be derived from the Richland County experience:

1. There is no reason to defer the setting up of a case-finding program because there is no sanatorium in the district. That the case-finding clinic is only a part of the tuberculosis control program is true. To complete the control program, the care and rehabilitation of the tuberculous patient must be provided for. But I am firmly convinced that a local sanatorium is neither a prerequisite nor a necessity for developing either a case-finding clinic or a complete control program. In fact, I believe that the tuberculosis hospital as a county project is not economically sound except in metropolitan areas. But the need for a case-finding program in non-metropolitan areas does exist. I believe that case finding is the horse that pulls the cart of the control program.

2. The program should be based on the county unit and should be operated as a permanent and integral part of the county health department, and, if any exist, of the city health departments. The county unit is of workable size. The health departments possess established organizations. Tuberculosis is a communicable disease, and measures for its control are the responsibility of the health department.

3. The program should be run in cooperation with private physicians in essentially the manner outlined. The finding of a communicable disease such as tuberculosis is not likely to attain highest effectiveness in any other way, surely not without the expenditure of much larger sums of money per case found. With the private physician cooperating by sending his patients suspected of having disease of the chest to the clinic for examination, the most fertile field for discovering cases can be exploited. Thus there is a logical and reasonable division of labor between the private physician and the clinic, with neither encroaching on the other's domain and each supplementing and complementing the other.

4. The clinic physician must be a specialist adequately trained in the characteristics of diseases of the chest and familiar with the epidemiology of tuberculosis. He does not necessarily have to be a resident of the county. In fact, a good many difficulties can be avoided if he is not in competition in his private practice with physicians practicing in the clinic area.

5. With such a program as I have outlined, it is possible to keep the cost per case found within reasonable limits and still approach an adequate coverage of the area. Aided by the repeated examinations of contacts my clinic is discovering an increasing percentage of cases of tuberculosis in the incipient stage, which is as vital to the effective control of the disease as to the hope of cure for the individual patient.

6. Lastly, it is possible—and desirable—to educate the public in the control of tuberculosis at the same time as the actual diagnosing goes forward. The finding of cases offers concrete evidence of the presence of the disease and demonstrates the possibility of controlling it. It cannot be too strongly emphasized that the creation of an enlightened and intelligent attitude toward the control of tuberculosis is one of the chief functions of any clinic. The way to treat any communicable disease is to bring it into the open and explain to the public how it is caused and how it can be prevented. Once the public understands what must be done and that it is possible to do it economically and without fuss, it will gladly lend its assistance to a program of control.

I think it best to obtain funds for case-finding work from the sale of Christmas seals, because the average

citizen is interested in the fate of the dollar which he spends for them. After a favorable public attitude so necessary for effective work is created, tax funds will probably be provided for the continuation and the necessary and reasonable expansion of the control program. I am firmly convinced that the New York state plan offers the best ultimate solution for the control of tuberculosis in the nonmetropolitan counties of Ohio and probably in most states. But it should not and will not materialize until enough of the nonmetropolitan counties have paved the way with sound case-finding programs.

This report describes one concrete attempt to solve the problem of tuberculosis control in nonmetropolitan counties and is presented with the hope that physicians and health officers may be encouraged to set up similar programs. The Richland County program almost certainly does not represent the final answer to the problem. But its success so far makes me believe that it is a long step in the right direction.

175 South Main Street.

ABSTRACT OF DISCUSSION

DR. ROBERT E. PLUNKETT, Albany, N. Y.: Physicians in charge of chest clinics too frequently fail to appreciate the importance of establishing appropriate relationship with practicing physicians. Nothing is more basic and more important than that the chest clinic have the active support of the practicing physicians. The more completely a clinic service is integrated with the field of medical practice, the greater will be the returns in profitable case finding and control. In the absence of such integration, optimum results can never be achieved. This statement is made after more than twenty years' experience in a service in which one of the requisites is cooperation with the medical profession. Such cooperation has resulted in virtually 100 per cent of the physicians practicing in the areas served by the New York State Department of Health clinics actively participating in our tuberculosis case finding and follow-up program. Dr. Bliss has wisely recognized the importance of this fundamental factor. It is obvious that because of this recognition the results which he has achieved have in no small part been due to this common understanding and the resultant good will of the practicing physicians. Superficially, Dr. Bliss's statement that 13.7 per cent of 1,200 new patients who were examined showed evidence of active tuberculosis is somewhat startling. It is apparent that a yield so much higher than the average in clinic service indicates some unusual condition. This point is emphasized by Dr. Bliss when he states that the rate is not an index of an excessive incidence of tuberculosis in Richland County. In other words, this percentage yield is probably due to the highly selected group of patients who had been referred to his clinics for examination. I am confident that as his program is extended, and it should be, this percentage yield will become much smaller but none the less profitable to the public health. It has been my experience that except for highly selected segments of the population, such as Dr. Bliss reports on, the percentage yield in clinically significant pulmonary tuberculosis has been found to be greater among patients referred to a clinic because of history of contact, plus those referred because of symptoms, than in any other group. It is impossible to overemphasize the importance of tuberculosis in the adult age groups. The New York State Department of Health has recognized the need for supplementing routine clinic service by the roentgenographing of groups of the adult population. When the present national emergency arose, plans were formulated to roentgenograph all men before they were inducted into military service as a part of the National Selective Service Act. An extensive study prompted the division to conclude that of the available methods for producing chest roentgenograms, namely 14 by 17 inch celluloid films, 14 by 17 inch paper roentgenograms and 4 by 5 inch and 35 mm. roentgen-photographic films, the 4 by 5 roentgen-photographic film is the most economical and most practical method for screening large groups of people.

ADIPOSOGENITAL DYSTROPHY

RALPH H. KUNSTADTER, M.D.

CHICAGO

A great deal of skepticism concerning endocrine therapy of the adiposogenital dystrophies has arisen because of extravagant claims and ill defined indications. This has led to the treatment of patients who did not present true endocrinopathies¹ and the use of endocrine products which are now known to be ineffective.²

Many children with small genitalia are unjustly labeled "pituitary type," Fröhlich's syndrome or adiposogenital dystrophy. We must not overlook the fact that the most common cause of obesity is overeating.³ We must realize that pronounced obesity in itself may conceal the actual size of the genitalia so that a false impression may result unless careful examination is carried out. We must also consider the limits of normal; that small genitalia in the prepuberal period may signify simply a physiologic retardation or delay in development, possibly at the expense of rapid growth (which is common in many of these children), a retardation that may undergo spontaneous correction.

What then is adiposogenital dystrophy? Babinski⁴ and Fröhlich over forty years ago described cases of obesity⁵ with hypogenitalism secondary to expanding lesions in the region of the pituitary body. A few years later Bartel applied the term adiposogenital dystrophy to this syndrome but other investigators were not convinced that the destruction of the pituitary alone was responsible for this condition.⁶ In the past twenty years a great deal of experimental evidence has indicated that the pituitary and the region of the hypothalamus are concerned with growth, sexual development, certain phases of metabolism and obesity, although the exact relationship of these structures to obesity is not clearly understood. In all probability adiposogenital dystrophy is a dysfunction of the pituitary gland involving both the anterior and the posterior lobes, originating in the pituitary, the adjacent hypothalamic region or both. Bauer⁶ argues against the impairment of certain hypothalamic centers or of the pituitary and believes that "the frequent finding of small or incompletely descended testis can be explained by the underlying abnormal genetic factor which causes obesity and which affects the endocrine glands in general and the gonads in particular." Could not the abnormal genetic factors be responsible for the endocrine disturbance? Although in Fröhlich's original patient pituitary tumor was present, intracranial hemorrhage, encephalitis, possibly toxic suppression or degeneration of the pituitary or adjacent structures following infectious diseases of childhood may result in this clinical syndrome. There are many instances in which no pathologic lesion was demonstrable clinically or at autopsy, and it has been my experience that the majority of cases are in this group. From a clinical point of view, children who show definite evidence of endocrine

dysfunction, that is, hypogenitalism associated with pronounced obesity which cannot be explained on the basis of overeating in a broad sense, may be considered as presenting adiposogenital dystrophy.

Adiposogenital dystrophy occurs more often in females than in males, but the latter are seen more frequently because genital infantilism is more conspicuous. The onset may occur at any age. Rarely there is a history of excessive weight at birth. Often there is a rather sudden and progressive increase in weight, beginning between the ages of 7 and 10 years, which is out of proportion to the food intake. The clinical picture of typical so-called Fröhlich's syndrome or adiposogenital dystrophy is familiar to all and does not need elucidation.

These patients are usually endowed with normal intelligence and may be indolent and good natured. Not infrequently they are introspective because of self consciousness.

There may be an increased carbohydrate tolerance due to decrease in the secretion of an insulin-antagonizing hormone.⁷ Schwarz, Neuman and Baum⁸ found a high concentration of fat metabolism hormone in their cases. The basal metabolic rate is variable. There may be fluid retention or the other extreme, diabetes insipidus, due to disturbed water and salt metabolism. There may be an elevation of blood chlorides and uric acid and a diminution of specific dynamic action of proteins.

Roentgenograms of the skull usually reveal no abnormal changes. Occasionally enlargement and erosion of the sella indicative of an expanding lesion, calcification within the sella, or a sella considerably smaller than normal may be present.

DIAGNOSIS

The diagnosis of adiposogenital dystrophy must be made with caution. Many patients do not present the typical picture described, and it is difficult to interpret borderline cases. A consideration of the developmental history is important in regard to disturbance of somatic as well as mental development.

The genitalia of the male patient should be examined in the recumbent as well as in the upright position, so that excessive adipose tissue may be retracted and migratory testes manipulated in the scrotum and their size estimated. Rectal examination is important. In the older male the prostate and seminal vesicles, and in the female the pelvic organs may be infantile. Hormone assay of the urine may suggest an endocrine disturbance. In primary hypogonadism there may be diminished excretion of either androgens or estrogens with an increased excretion of gonadotropic substance, whereas in primary pituitary deficiencies there may be a diminished excretion of both.

TREATMENT

The treatment of adiposogenital dystrophy depends on the age of the patient and the presence or absence of organic disease.

The aim of endocrine therapy is restoration of function by stimulation or replacement. In treating the prepuberal patient several factors must be taken into consideration. Stimulation is desired and untoward effects are to be avoided. Excessive hormone may suppress the pituitary and also cause atrophy of the gonads

as the result of direct action.⁹ Less frequently precocious development¹⁰ with premature cessation of growth may occur. Because of these dangers both estrogenic and androgenic hormones should be avoided in the *prepuberal period*. Stimulation of the gonads by the combined administration of anterior pituitary extract and either chorionic or equine gonadotropin should be attempted. The former may supply a gonad stimulating fraction not present in either of the latter. In view of the metabolic disturbance present in these patients, I believe that anterior lobe extract containing not only the gonad stimulating but possibly the metabolic fraction is preferable. If there is an associated diabetes insipidus, posterior lobe extract (pitressin) may be administered.

For the puberal patient when it is desirable for cosmetic and psychologic as well as physical reasons to produce a more rapid appearance or improvement in the secondary sex characteristics, androgenic or estrogenic substance should be combined with the gonad stimulating preparations, the latter also possibly offsetting any local degenerative effect that the androgens or estrogens might have on the gonads.

In the castrate, whether surgical, cryptorchid or congenital, gonad stimulating hormones are of no value and it may be necessary to administer androgenic or estrogenic substances in large doses indefinitely.

The mode of administration and duration of treatment depend on the age of the patient and the response. In the prepuberal male or female the treatment may be a matter of weeks or months before either subjective or objective improvement results. Treatment should be interrupted at various intervals as refractoriness may develop.

In the rare case of intracranial tumor or cyst involving the pituitary, roentgen therapy or surgical intervention may offer some hope of improvement.

Dietary management and correction of faulty eating habits are essential in all obese patients regardless of the etiology.¹¹ A high protein, low caloric diet should be prescribed.¹² If there is evidence of water retention, sodium chloride should be restricted and potassium chloride or acetate substituted (the latter also having a diuretic effect). I have found that amphetamine sulfate is a valuable aid in controlling the abnormal appetite of many of these patients.¹¹ It has been my experience that, unless there is definite evidence of hypothyroidism, thyroid is of little value and may even be harmful. Also it frequently stimulates the appetite.

CONCLUSION

It should be repeated that not all obese children outgrow their fatness and not all children with hypogonadism improve spontaneously. If one reviews the case reports of adult hypogonadism, frequently one finds that the disturbance dates back to childhood. If the history is considered, if a careful physical examination is performed and if the laboratory results are properly evaluated, I do not believe that obese but otherwise normal children will be subjected to unnecessary endocrine therapy.

HYPOTHYROIDISM IN CHILDHOOD

E. KOST SHELTON, M.D.

LOS ANGELES

For purposes of clarity, let us assume that there are three types of hypothyroidism during childhood, namely cretinism, juvenile myxedema and borderline hypothyroidism. As a matter of fact they are all one and the same disorder modified according to (a) the severity and (b) the length of time during which the patient has been subjected to the deficiency. Because we are dealing with a hormone whose purpose it is not only to develop the organism during the most plastic period of its existence but also to maintain it in functional equilibrium, one can readily appreciate the diagnostic variables to be encountered in a disruption of such a mechanism at any age.

Let us first consider the degree of severity. Until recently the more conservative observers were unwilling to concede any form of hypothyroidism which could not easily be classified under cretinism or myxedema. When analyzed closely, such a stand is not tenable. In common with most other secreting organs there is a margin of safety between the physiologic requirement of the thyroid and its functional capacity, but there is a threshold below which the gland may be said to be embarrassed rather than actually devoid of function. Such a mild disturbance encountered at any age but more commonly in early adolescence cannot be classified under cretinism and rarely develops myxedema.

The element of time is of equal importance. A mild degree of hypothyroidism for a short period, at any stage of development, will likely not be reflected objectively in the somatic or mental makeup. Over a period of years, however, even a mild degree of thyroid deficiency must leave its mark on both the soma and the psyche. A severe degree of deficiency, as that which follows total ablation of the gland (but which also occurs spontaneously), may completely incapacitate the patient within a few months, while partial or moderate deficiencies may go unrecognized for years. Thus the frequent confusion regarding the early diagnosis of other than the most severe case.

Classic hypothyroidism or cretinism and juvenile myxedema have been described for so many years by so many observers, without any new or startling innovations, that I shall refrain from going into detail in a consideration of this type of case. Suffice it to say that the classic hypothyroid child is still the dwarfed, lethargic, edematous, pot bellied, alabaster skinned, constipated imbecile it has always been. But we must keep this picture in mind since the study of disease entities begins with the classic case and hypothyroidism is no exception. Most observers are now agreed on the consistency with which certain laboratory and roentgen data are discovered in such classic cases.

BASAL METABOLIC RATE

Either in a closed chamber or by the open method, when estimated under ideal conditions (usually impossible) by any method of calculation, the oxygen consumption will be found to be much lower than in a similar group of normal children. In other words, the basal metabolic rate will be found to range between minus 20 and minus 40 per cent.

Read in the Panel Discussion on Endocrine Disorders of Adolescence before the Section on Pediatrics at the Ninety Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

BONE AGE

Every child with severe untreated hypothyroidism will show retardation of osseous development when the disorder has existed for a period long enough to be reflected in the somatic makeup.

BLOOD SERUM CHOLESTEROL

Most, if not all, observers in recent years have demonstrated blood serum cholesterol values ranging from 50 to 200 per cent above the average normal. Individual variations and different methods of determination make it difficult to arrive at actual figures. In my practice the abnormal values usually range from 250 to 500 mg. per hundred cubic centimeters.

URINARY EXCRETION OF CREATINE

Children with severe hypothyroidism, untreated, excrete considerably less creatine in the urine than a similar group of normal children.

THE MILD (OR BORDERLINE) CASE

If this is all true and, generally speaking, it is, although there are some exceptions, why would it not be easy to make diagnoses in mild or borderline cases by a mere modification of the foregoing? The basal metabolic rate is both mechanically and mathematically difficult to obtain in the average child, particularly the mentally inapt child. Children, technicians, machines and methods of calculation vary and so, unfortunately but inevitably, do results. It is therefore not a practical diagnostic procedure in the young child. In older, more tractable, children and in adolescence it is a part of the diagnostic procedure. Even here, too much dogmatism is employed in an interpretation of the findings. I have seen numerous children with very low readings who I am convinced did not suffer from hypothyroidism. I have seen children with normal or moderately high readings who have profited by thyroid administration. Never make a diagnosis or guide your dosage for any length of time by an estimation of the basal metabolic rate alone. Some individuals are veritable thyroid eaters and may take many times the normal physiologic dose without objective alteration of the metabolic processes. Others appear most sensitive to thyroid administration. It has been my experience that children who really need thyroid are more sensitive to it than the normal, particularly in the early weeks of treatment.

Bone age continues to be the most objective evidence of the developmental status of the child; but, while children with true hypothyroidism of long standing will have retarded osseous development, the reverse is not necessarily true. In my original paper on this subject some ten years ago and repeatedly since, I have advised that the interpretation of such a finding should be subjected to the same criticism as any other diagnostic procedure. It has been my misfortune, however, to see as much diagnostic dogmatism placed on shades of variation from the average normal in this subject as in the case of the basal rate. It may be employed safely as follows: If the child is retarded two years or more according to some accepted standard (and all of the standards are within a few months of one another), try to prove or disprove hypothyroidism in the patient by every other means. Do not use the wrist or any other roentgenogram as the sole diagnostic criterion. On the other hand, even severely hypothyroid patients will have no reflection of their difficulty in the osseous

development unless the condition has been present for a number of years. So it is even possible for a child with severe but recent hypothyroidism to have a normal bone age.

The blood serum cholesterol is not pathognomonic of mild or borderline hypothyroidism because values vary even in the classic case. When all other causes of high blood cholesterol have been ruled out, values have been found to vary in a large group of normal children. Persistent high blood cholesterol values otherwise unaccounted for (in my practice over 220 mg. per hundred cubic centimeters) are very suggestive, however, particularly if corroborated by other physical or laboratory criteria.

I have estimated the urinary creatine excretion in over a thousand children and still rest on my original findings. The creatine excretion is very low or absent in the classic hypothyroid child. But it is also low or absent occasionally in children who are dwarfed or puny but who otherwise do not fit into the classic hypothyroid group. Therefore, just as the bone age and the cholesterol, the creatine excretion is informative but not diagnostic.

Variations from the classic clinical picture are important diagnostic criteria. There may be something in the history, the appearance of the skin, the temperature, the pulse, the hair, the stature, the posture, the teeth or the voice to initiate the investigation. Overweight is a very poor diagnostic sign.

Finally we come to the therapeutic response. Classic hypothyroid children, with few exceptions, respond promptly to ingested thyroid. The oxygen consumption increases, the basal metabolic rate rises, the bone age in relation to chronological age increases, the blood serum cholesterol falls, the urinary excretion of creatine increases, the patient's height increment is enhanced, the infantile characteristics disappear and cerebration improves. But what of the mild or borderline case? Here as well the symptoms subside, but mere subjective improvement is not enough to satisfy the astute observer. For this reason every attempt should be made to arrive at some conclusion before beginning treatment. Too many children with developmental anomalies, birth injuries, mongolism and wholly unallied disorders, to say nothing of constitutionally inadequate children, are put carelessly on thyroid without an adequate investigation.

Amelioration of symptoms and alteration of laboratory and roentgen data are therefore diagnostic criteria of major importance. But even here we have our diagnostic difficulties. Evans has shown that thyroid is ineffective when administered to hypophysectomized animals. This is probably why some dwarfs fulfilling most of the criteria of hypothyroidism do not respond to thyroid administration. Also Smith and others have shown that administration of an anterior pituitary fraction complements the action of thyroid at least so far as the growth process is concerned. For these reasons we need a potent pituitary fraction to enhance our therapeutic armamentarium in the treatment of complicated hypothyroidism. To my knowledge such a product is not on the market.

The dose of thyroid is another variable, but something between one-half and three grains (0.03 to 0.2 Gm.) a day has been an adequate range in my practice. It may be given in a single dose once a day. All reputable brands of desiccated thyroid are efficacious,

but the clinician should familiarize himself with one brand before prescribing thyroid indiscriminately. In my judgment, thyroid should be administered alone and not with other usually inert glandular material. Dosage should be regulated by repeated clinical observations and occasional laboratory tests.

CONCLUSION

The diagnosis of mild or moderate hypothyroidism consists of a series of tests, all of which are highly informative but none of which are conclusive. When considered with the history and physical picture, one is frequently able to arrive at a fairly definite conclusion. The objective therapeutic response to thyroid may be necessary to establish a diagnosis, although congenital absence or disease of certain elements of the anterior pituitary may nullify the effect of thyroid even in a hypothyroid child. Treatment of all forms of childhood hypothyroidism should be early, adequate and persistent. Complete rehabilitation is possible under ideal conditions.

760 North Beverly Glen Boulevard.

GYNECOLOGIC PROBLEMS OF ADOLESCENCE

EMIL NOVAK, M.D.
BALTIMORE

No sharp time limits can be fixed for the period of adolescence, which represents a transition phase between puberty and full maturity. The latter themselves are periods subject to no fixed chronological laws. The changes of puberty involve far more fundamental phenomena than the mere appearance of the first menstruation (menarche). Many of these phenomena are carried over into adolescence. As a matter of fact, the gynecologic and endocrine problems of adolescence are essentially those of puberty. Moreover, they are practically all of endocrine causation, emphasizing again, if it needs further emphasis at the present day, how fundamental a role endocrinology plays in modern gynecologic practice.

Important as are the endocrines in the anatomic and physiologic phenomena of adolescence, there is one other factor which can never be overlooked in the interpretation of functional disorders at this epoch. I refer to the psychologic element. Even in the minds of the public, the term "adolescent psychology" carries with it a distinctive connotation, as popularized, for example, in the penetrating literary delineations of Booth Tarkington. It indicates a period of romanticism and idealism, impressionability, hero worship, day dreaming and other such traits. This transient phase, amusing as it may be to the child's elders, can never be overlooked as a possible influencing factor of adolescent functional disorders. As a matter of fact, it may lead to consequences which in the occasional case are not only not amusing but may actually be tragic.

If, for example, the girl's hero worship is centered on a distant movie star, the infatuation is certainly more amusing than harmful. But if, in a lower stratum, a girl bestows her idolatry on the neighborhood bully,

a bitter price may be exacted by the object of her hero worship. The purely psychologic aspects of adolescence, which must envisage a consideration of the newly awakened force of sex consciousness, will be considered by others in this symposium, but they frequently obtrude themselves into the interpretation of the functional gynecologic problems of adolescence.

From a purely physiologic point of view the period of adolescence may be brief or virtually nonexistent, as in many girls menstruation and ovulation may be normal in character and rhythm from the beginning. The anatomic changes, on the other hand, are always gradual. In some girls the appearance of the first menstrual period is preceded for many months by increasing development of the breasts, genital and axillary hair growth, rounding of the figure and other secondary sex manifestations. In others this preliminary phase is brief, the general developmental changes occurring chiefly after rather than before the menarche itself.

ABNORMALITIES IN HEIGHT

During adolescence there is an increasing restraint on pituitary growth hormone activity as a result of the increasing activity of the ovarian hormones. Various abnormalities in this hypophysiogonadal balance may bring about excessive or deficient skeletal growth, with varying degrees of gigantism or dwarfism. Aside from their purely objective aspects, such abnormalities often have profound psychologic repercussions, with the development of complexes characterized by morbid self consciousness concerning the affliction. Psychotherapy must often play an important part in the management of these conditions. The unusually tall girl, moreover, is prone to develop postural difficulties because of her tendency to stoop to make herself seem shorter. These postural difficulties are often later expressed in back-ache, lower abdominal discomfort, and even in the form of dysmenorrhea.

DYSMENORRHEA

The role of the psyche in the production of primary dysmenorrhea is unquestionably a most important one, although only a minority of gynecologists accept the view that all cases of this disorder are of psychogenic etiology. The best prophylactic against this type of dysmenorrhea is proper training of the girl, preferably by her mother, as to what menstruation signifies and what it does not signify and, above all, that the function is not characteristically associated with pain and that it should interfere but little with the life activities of the girl. Unfortunately this ideal training is not available to most young girls in the puberal and adolescent years. Many mothers are loath to discuss these problems with their daughters and only too often are themselves ignorant of simple facts about the menstrual function. If any advice is given, it is far more apt to consist of admonitions tending to make the girl coddle herself during menstruation. Thus the impressionable youngster is apt to look on menstruation as a time when she should actually be unwell, and a step is taken toward the development of primary dysmenorrhea. Various forms of psychic trauma to which the adolescent girl is so often exposed may accelerate her progress toward dysmenorrhea.

Almost as important, perhaps, is the constitutional factor, as expressed in the general health level of the girl, and her habits as to exercise, recreation, study, food and sleeping hours. The foundation of many cases

not only of dysmenorrhea but also of general neuroticism and invalidism is laid in adolescence. The young girl who is so ambitious to excel in her scholastic work that she neglects recreation, sunshine and proper sleep in this developing epoch of her life often pays the penalty later on as a menstrual invalid of one type or another.

These statements may seem trite and old fashioned now that the endocrine explanation of primary dysmenorrhea occupies the limelight of discussion. The mechanism of primary dysmenorrhea, however, is still a mystery in spite of the fact that studies of the effects of the ovarian hormones on the uterine musculature have appeared to have a close bearing on the problem. By all but a few dissenters estrogen is accepted as the normal stimulant of uterine contractility, while progesterone is the normal inhibitor. If, as seems likely, the pain of dysmenorrhea is the result of exaggerated painful contractions of the uterine musculature, the natural suggestion would be that dysmenorrhea is brought about by a relative excess of the estrogen effect or a deficiency of progesterone. The factor of sensitivity of the individual uterine musculature to these hormones must also be considered, though there is no way to evaluate this clinically.

The hormone treatment now so popular in dysmenorrhea is based on the aforesaid premises. It consists in the employment of substances which, so far as the uterine muscle is concerned, are supposedly antiestrogenic in their effect (preparations of testosterone) or of preparations which, from the same point of view, are synergistic with progesterone (preparations of progesterone, testosterone and chorionic hormone). Few gynecologists are altogether satisfied with the results of such therapy in spite of the fact that it appears to be of genuine value in many cases. It cannot be too strongly emphasized that dependence on endocrine treatment alone, with disregard of psychic and constitutional measures, is certainly not justified in the present state of our knowledge and is quite sure to result in a large proportion of failures.

Many years ago, when the roles of estrogen and progesterone were first being discussed, I called attention to two features of primary dysmenorrhea which seemed paradoxical. One of these is the fact that in certain conditions in which there is a relative and perhaps decided excess of estrogen and perhaps a complete absence of progesterone, and in which one might therefore expect an exaggerated contractility of the uterus, pain is characteristically absent. This is conspicuously the condition of affairs in most cases of functional bleeding.

The second puzzling feature was the fact that, in a considerable proportion of cases, primary dysmenorrhea does not begin at the menarche but a considerable time, from a few months to several years, after the first menstruation.

Can we reconcile these facts with the present day endocrine theory of dysmenorrhea? In the largest group of cases of functional bleeding ovulation does not occur, and more recently we have learned that ovulation may remain in abeyance for a considerable time after the inauguration of menstruation. Thus it appears that primary dysmenorrhea is a disease of ovulating women and that the anovulatory cycle, prone though it is to exhibit aberrations characterized by excessive bleeding, is not associated with pain. The correctness of this assumption has been established by

Sturgis and Albright¹ by means of endometrial studies, although others like Wilson and Kurzrok² had previously expressed this view. Sturgis and Albright were able to prevent primary dysmenorrhea for a particular cycle by inhibiting ovulation with large doses of estrogen in the early part of the cycle. Their good results have been repeated by others, though not with such invariable success.

These advances have not solved the riddle of dysmenorrhea either as to its mechanism or as to its treatment. They have, however, emphasized the real importance of the endocrine factor. By means of large doses of estrogen begun early in the cycle it appears possible to inhibit ovulation and to make the next period painless, but repetition of the treatment, aside from other obvious disadvantages, is often unsuccessful. Conceding that primary dysmenorrhea is characteristically a disease of ovulating women, we are still in the dark as to its underlying cause. Various hypotheses have been suggested, such as that of imbalance between the two ovarian hormones, with perhaps resulting abnormalities in the partition of the estrogenic principles, but nothing of a definite nature has been established, so that we shall have to struggle with this common and distressing problem of dysmenorrhea for some time to come.

AMENORRHEA

This is not the place to attempt a complete discussion of the possible causes of amenorrhea in adolescence. Here we most commonly have to deal with the primary type, but the secondary variety is not rare in girls still within the adolescent phase. From a practical point of view the chief admonition would be not to resort too quickly to ovarian or gonadotropic therapy in young girls. The first menstruation not infrequently does not appear until the age of 16, and even the age of 17 is not exceedingly rare for the menarche. In my own work endocrine therapy is rarely resorted to before the age of 17, except perhaps for the employment of small doses of thyroid. This does not mean that other measures, such as those directed toward raising the constitutional health level in every possible way, are to be neglected, for this would be most unwise. Nor does it mean that an obvious or demonstrable endocrinopathy, such as hypothyroidism or dyspituitarism, should not be studied and treated according to accepted methods.

The fact remains, however, that a great many girls of 15 or 16 are unnecessarily subjected to "shots" of all sorts, that such treatment in itself is generally ineffective, and that when menstruation does occur following such treatment it would probably have occurred without it. Every conservative gynecologist is pessimistic about the organotherapy of endocrinopathic amenorrhea in general, and too early and unnecessary resort to such treatment in young girls may engender undesirable psychologic sequelae. In the treatment of all menstrual difficulties in adolescent girls, the physician can perform an incalculable service by reassuring explanations not only to the patient but to the mother as well, since the latter so often has wrong ideas as to the possible dangers of amenorrhea in itself. Especially important is it to stress the fact that the mere absence of menstruation is in itself harmless, for on this point many wrong ideas are still prevalent.

FUNCTIONAL BLEEDING

Excessive menstrual bleeding is a frequent occurrence in young girls, and with few exceptions it is of functional nature. The diagnostic problem is far simpler at this age epoch than it is in the case of abnormal bleeding near the other extreme of menstrual life, when so many other possible factors, some of serious import to the patient, must be considered. Simple rectal examination will usually, in the case of young girls, eliminate the relatively rare neoplastic lesions which might at times cause excessive menstruation. While this should be done, few mistakes will be made if the functional nature of the bleeding is taken for granted.

The common mechanism of adolescent functional bleeding consists, in brief, in a failure of ovulation, with resulting excess of the estrogenic hormone and an absence of progesterone. In other words, it represents an exaggeration of what happens in the anovulatory type of cycle so often seen in the early years of menstrual life. The fact, for example, that a girl begins to menstruate at 14 does not necessarily mean that she is susceptible of fertilization if insemination should occur, for she may not begin to produce eggs for a considerable time after the menarche. That the anovulatory type of cycle of which functional bleeding is so often an aberration is not infrequent in the early months or even years of menstrual life has been well established, but there are no available data as to its relative incidence as compared to the common ovulatory cycle.

The disorder therefore revolves around the failure of ovulation, of whose hormone causes we still know little, but there is little doubt that the underlying disturbance is in the anterior hypophyseal lobe. No very effective method of inducing ovulation in the nonovulating human female is as yet available in spite of the enthusiastic reports of some writers as to the efficacy of the equine gonadotropic preparations (pregnant mare serum). The immediate purpose of most methods of treatment is to limit the abnormal bleeding rather than to induce ovulation, and for this purpose three chief types of hormonal preparations have been employed: progesterone, testosterone and the chorionic hormones found in pregnancy urine. In general the results must be evaluated as far from satisfactory but in a considerable proportion of cases sufficiently effective to tide the girl over her frequently temporary phase of excessive bleeding.

The tendency in most cases of functional bleeding seen in adolescence is toward readjustment of the endocrine balance with then the occurrence of ovulation and the establishment of essentially normal bleeding. For this reason it is a wise policy to abstain from endocrine therapy in the frequently observed cases of mild degree in which the blood loss is so moderate as to produce no demonstrable degree of anemia. Unfortunately, more active measures are often made necessary by the profuse and even exsanguinating bleeding which may occur. Curettage may be indicated for the immediate control of the bleeding, temporary though this relief may be, while hematinic measures and sometimes transfusion are not infrequently called for. More radical measures, such as hysterectomy or radiotherapy, are rarely to be thought of, although many excellent gynecologists resort to small doses of radiotherapy in the more severe cases. In general, however, radiologists agree with gynecologists that radiotherapy should be a method of last resort, as even very light dosage may produce permanent effects in the occasional case.

OBESITY

The problem of the fat girl is a common one in gynecologic practice, especially since so many of this group of patients suffer also from amenorrhea or other menstrual abnormalities. The management of the amenorrhea cannot be separated from that of the obesity. This is not to say that they are invariably associated, for this is the case in only a proportion of the patients. As with obesity in general, the milder forms may be of exogenous causation, with overeating as the most important factor. In the majority of patients who are brought for medical advice, however, endocrine factors of one sort or another are concerned.

Careful study will often permit of classification on a reasonably sound basis. In the majority of instances of pronounced obesity the cause will be designated as pituitary, hypothalamic or a combination of the two factors (hypophysiohypothalamic). It is in the latter two groups that we must place most of the extreme cases, as when girls of 16 and 17 reach a weight of 200 pounds or more. In obesity of this extreme grade, menstruation may be entirely normal, scanty, irregular or absent altogether, indicating presumably the degree of participation of the pituitary sex hormones.

The fact that both menstruation and ovulation may be entirely normal, that disturbances of fluid balance are not infrequently present, that obesity of this type may occur with tumors in the parapituitary region and as a sequel of encephalitis or basal meningitis—all these point circumstantially to the fact, for which there is also experimental evidence, that the seat of trouble is in certain parapituitary areas of the midbrain, probably in the hypothalamic region. For such types of obesity there is no direct endocrine treatment, but efforts may be made, usually unsuccessfully, to treat the amenorrhea. Aside from this the employment of such measures as low caloric diet, exercise, massage and perhaps the cautious employment of thyroid would seem to represent our whole armamentarium.

In the more moderate grades of obesity, we have often to do with pituitary, thyroid or ovarian factors. This is not the place to elaborate on the available methods of study and management of such cases. One point seems to me well worth stressing. Puberty, like the menopause, represents a phase at which there occurs a readjustment of the endocrines. As a result of this reshuffle, many a girl who has been obese before puberty assumes essentially normal proportions afterward, and menstruation may be established normally. On the other hand, puberty may bring about an accentuation of a preexisting endocrinopathy with persisting and increasing obesity and often amenorrhea.

The moral is that we should be slow to resort to endocrine therapy in prepuberal or puberal patients, and that treatment should be restricted to such limitation of diet as the active life of a young girl will justify, together with exercise. The cautious employment of thyroid, especially when there is evidence of hypothyroidism, is indicated in some cases.

The morbid self consciousness of many fat girls concerning their affliction must be combated with reassuring psychotherapy, and especial care should be taken to warn against the extreme and inadequate dieting to which many youngsters subject themselves in their desperate efforts to reduce. Aside from other dangers, the ovaries are extremely sensitive to nutritional and vitamin deprivation, and this in itself may be a cause of amenorrhea, as I have observed in a good many cases.

HIRSUTISM

While not as common as some other adolescent disorders, there are few afflictions which can be the cause of more mental distress than hirsutism, especially when it involves the face. The adrenal cortex and the pituitary appear to be incriminated in most of these cases, but no effective endocrine treatment is as yet available. In the frequent mild form involving the upper lip alone, relief may be obtained by the painful, time consuming and expensive method of electrolysis, while in other cases depilatory and other cosmetic technic is available. In the extreme grades frequent close shaving may be necessary.

Hirsutism may be noted in girls who otherwise are typically feminine, with normal menstruation and ovulation, well formed breasts and normal genitalia. In itself it is not to be looked on as evidence of a masculinization tendency, as so many of these sufferers wrongly fear. It is only when combined with other intersexual manifestations, such as hypertrophy of the clitoris, flat breasts and a deep voice, that it is to be looked on as a part of a masculinization syndrome.

BREAST ABNORMALITIES

Unusually flat breasts in otherwise normally developed girls are the source of frequent unhappiness, as is the opposite condition, in which the breasts are of unusually large or even enormous size. The fact that both of these two conditions are so often noted in otherwise normal girls, with normal menstruation, points to the fact that the causative factor is not an abnormal deficiency or excess of the ovarian hormones on which breast development depends. Rather does it indicate that the breast tissues of the particular girl are for some reason unduly refractory or abnormally sensitive to the estrogenic growth stimulus.

While the flat breasted girl is often treated with some form of estrogen administration, either hypodermic or percutaneous, the results are not usually significant, and my experience has been that they are rarely better than can be obtained by such simple measures as frequent massage, designed to promote growth by increasing the blood supply.

Nor is there any satisfactory endocrine therapy for the abnormal hypertrophy occasionally seen as a local exaggeration of the puberal secondary sex phenomena. When not too pronounced, the problem can be reasonably well taken care of by some form of breast uplift. In the extreme forms, in which the breasts may hang to or beyond the waist, plastic operations may be necessary, but these require special skill and experience to secure satisfactory results.

SUMMARY

There are few disorders, developmental or functional, which are distinctive of the period of adolescence, but the rather special psychology of the adolescent girl gives these disorders an added importance at this phase of life, and the type of management may influence greatly the later life of such patients. Among the major problems discussed are the menstrual disorders, but others frequently encountered, and briefly considered in this paper, are abnormalities of body growth, obesity, abnormalities in breast development and hirsutism. A reshuffle of the endocrines takes place at the puberal epoch, and conservatism must be the guiding motif in endocrine therapy at this phase of life and also in adolescence.

ENDOCRINE TREATMENT OF
CRYPTORCHISM

WILLARD O. THOMPSON, M.D.

AND

NORRIS J. HECKEL, M.D.

CHICAGO

In 1939 we¹ reported on the status of glandular therapy in patients with undescended testes and compared our results with those reported in the literature. In contrast to the 61 per cent of successful results of other observers we were able to produce descent in only 20 per cent of our cases and in only 27 per cent of those occurring in patients under 16 years of age. We were not able to produce descent in any instance in which the testis was intra-abdominal, although a high incidence of successful results (55 per cent) had been reported in patients with testes of this type. We concluded that glandular therapy would produce descent only in those testes which would descend by the time of puberty without treatment; namely, those which were not retained by mechanical factors. Nevertheless the treatment appeared valuable because it made it possible to determine at an early age whether operative procedures would be necessary or not in order to get the testis into its normal environment. Our investigation of this problem has continued and new patients have been observed. Several of the patients previously reported on have undergone orchiopexy. We may therefore check the accuracy of our previous conclusions and make any additions that may be warranted by further experience.

DATA

We have observed the effect of treatment in 89 undescended testes in 67 patients varying in age from 10 months to 37 years. Fifty-two patients were under 16 years of age. In 25 patients the condition was originally bilateral, but in 3 of these the position of one of the testes had been corrected by orchiopexy before the patient reported to us. Fifty-three of the patients showed normal body contour, 8 patients were of the Fröhlich type and 6 patients were eunuchoid. Eunuchoidism did not become evident until the time of puberty. The secretion of sex hormone at this time apparently exerts an important influence on the growth of the epiphyseal centers in the vertebrae as well as in the long bones, thus affecting the relation between the length of the trunk and the length of the extremities. Of 9 patients over 16 years of age with bilateral cryptorchism, 6 patients were eunuchoid in type while the remainder showed normal development of the penis, musculature and skeleton. All of them, however, showed some evidence of sex hormone deficiency.

Preparations Used.—This study is limited to our experience with chorionic gonadotropin. We used the products of four manufacturers.² Several patients who were treated with other types of glandular products or by surgery alone are not included here; neither are patients with migratory testes.

From the Departments of Medicine and Surgery, Rush Medical College of the University of Chicago and the Presbyterian Hospital.

Read in the Panel Discussion on Endocrine Disorders of Adolescence before the Section on Pediatrics at the Ninety Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

2. A. P. L. of Ayerst, McKenna and Harrison, Follutein of E. R. Squibb and Sons, Korotrin of Winthrop Chemical Company and Franturon of the Schering Corporation.

RESULTS

Our proportion of successful results has remained about the same, namely 24 per cent for the total number of undescended testes and 27 per cent for the total number of patients. Since the response bears some relation to the age of the patient and the location of the testis before treatment, our results may be discussed under these headings.

Relation Between Age and Response.—A higher percentage of successful results was noted before than after the age of puberty (table 1). Thus, in 34 patients 10 years of age and under, descent occurred in 14 of 44 undescended testes (32 per cent) while in 15 patients 16 years of age and over, descent was observed in only 4 of 24 undescended testes (17 per cent). The difference is not so great if the patients 11 to 15 years of age are included in the younger group. The higher incidence of descent before puberty may be readily explained. At the age of puberty hormonal factors normally come into play which cause descent of all those testes not retained by mechanical factors. As a result, the incidence of undescended testes in untreated patients is less after the age of puberty, and the only patients in whom any response to chorionic gonadotropin might be expected after this age would be those with hypopituitarism and associated hypogonadism.

TABLE 1.—*Relation Between Age of Patient and Response to Treatment with Chorionic Gonadotropin*

Age, Years	Number of Patients	Number of Patients Showing Descent of Testis	Number of Undescended Testes	Number of Testes Showing Descent
0-5.....	8	2	12	2
6-10.....	26	10	32	12
11-15.....	18	3	21	3
16 and over.....	15	3	24	4
Totals.....	67	18	89	21

Only 3 of our patients showed descent after the age of puberty, and all of them were eunuchoid men 23, 25 and 33 years old respectively. In the 23 year old patient 1 testis descended from about the midcanal, and in the 25 and 33 year old patients 1 descended from the abdomen and 2 from a position over the external oblique. Descent of the testes in these instances was associated with genital growth. In other words, by administering chorionic gonadotropin we had supplied artificial stimulation to the testes which normally comes into play spontaneously at the time of puberty. When cryptorchism in men is associated with primary hypogonadism, descent of the testis may sometimes be produced with testosterone propionate.

Relation Between Position and Response.—In table 2 it may be seen that there is a definite relation between the position of the testis and the response to glandular therapy. Our highest percentage of successful results was noted when the testis was in the canal or between the lower end of the canal and the upper end of the scrotum (36 per cent). Up to the present time we have been able to produce descent in only 2 of 34 intra-abdominal testes with chorionic gonadotropin (6 per cent) in spite of the fact that reports in the literature indicate descent in 55 per cent of such cases on the average. Testes deflected in abnormal positions have responded fairly well to treatment. Thus 35 per cent of those deflected over the external oblique have descended as did 1 of 4 that were directed toward the perineum. In this respect our results differ from those

which we have previously reported.¹ Perhaps in some instances a testis which was outside the canal could be deflected so easily over the external oblique that we erroneously concluded that this was its position. Several factors may be involved in the relationship between anatomic position and response to glandular therapy. When the testis remains in the abdominal cavity for a considerable length of time it may be damaged and incapable of showing much response to treatment. In occasional instances we have been unable to find any testis within the abdominal cavity at operation. Testes deflected in abnormal positions might be expected to progress farther in their abnormal direction following treatment, but this is certainly not always the case.

It follows from these observations that:

1. If the testis is in the canal or outside the canal, the results of glandular therapy are fairly satisfactory. Our data have not been analyzed to determine the relation between the position in the canal and the response to glandular therapy, but it is our impression that the lower the testis lies in the canal the better the response to treatment.
2. If the testis is in the abdominal cavity, it is unlikely that descent will occur with glandular therapy.

FINDINGS AT OPERATION IN UNSUCCESSFUL CASES

Twenty-five patients in whom the testes failed to descend with chorionic gonadotropin have undergone an orchiopexy. In 5 the operation was bilateral, making a total of 30 orchiopexies. As in our previous smaller series, anatomic factors were found which may have been related to the failure of descent. These included:

1. Fibrous bands which not only immobilized the testis but shortened the cord by producing adhesions to surrounding structures (all patients).
2. Abnormal direction of the peritoneal process (11 patients), which in 9 patients was turned upward over the external oblique, in 1 lay over the rectus sheath and in 1 was directed toward the perineum.
3. Absence of the external ring (1 patient).
4. Absence of testis (2 patients).

Until more precise information is available concerning the normal mechanism of descent it will be impossible for us to give a satisfactory explanation of our findings at operation in unsuccessful cases. In many instances the peritoneal process extended a considerable distance below the level of the testis, and it is of course well known that during normal development the peritoneal process precedes the testis into the scrotum. It is possible that fibrous bands may have prevented the descent of the testis along the peritoneal process. The abnormal deflection of the peritoneal process in many of the patients suggests that during embryonic development the scrotal fibers of the gubernaculum may have failed to appear. However, it is necessary to preserve an open mind on this problem because some testes that were deflected over the external oblique descended during the administration of chorionic gonadotropin.

PITFALLS IN DIAGNOSIS

There are two important diagnostic considerations:

1. The determination of whether or not the patient has true cryptorchism, and
2. The recognition of the accurate position of the testis.

It is important to exclude patients with pseudocryptorchism. (We have a separate series of 40 such patients.) This condition is present when the testis moves spontaneously or can be made to move between the scrotum and a higher level. These migratory testes

move permanently into the scrotum at the time of puberty and should not be included in a study of true cryptorchism. In some instances of pseudocryptorchism the testes may retract into the abdomen, simulating intra-abdominal cryptorchism. Since we used larger doses of chorionic gonadotropin than many observers, the only way we can account for our lower percentage of successful results is by difference in diagnostic criteria. In order to exclude migratory testes and determine the correct location of the testis, it is desirable to examine the patient in the upright position on at least two different days. Testes which lie over the external oblique are usually freely movable just under the skin. A hernial sac is not infrequently associated with failure of descent of the testis and usually extends below the testis. Occasionally the attention of the patient or the mother is directed to an undescended testis by the sudden development of a strangulated hernia.

CAUSES OF CRYPTORCHISM

The response to glandular therapy and the findings at operation suggest that there are two causes for cryptorchism:

- 1. A hormonal deficiency.
- 2. Anatomic abnormalities.

onic gonadotropin? There are several arguments in its favor:

- 1. The testis can function normally only in the environment of the scrotum.
- 2. It is therefore logical to assume that the earlier the testis is brought into the scrotum the more likely it is to be normal.
- 3. With glandular therapy it is possible to determine at an early age whether operative procedures are necessary or not. If there is no mechanical obstruction the testis will descend with glandular therapy alone (about one fourth of the cases).³ If it does not descend, operative procedures are necessary and are facilitated by the enlargement of the parts produced by glandular therapy. In spite of all the work done in the past twelve years on the treatment of undescended testes, the notion still persists in many quarters that the condition is of no consequence and will be outgrown. We are unable to subscribe to this point of view.

The chief argument against glandular therapy is that in order to produce descent it is usually necessary to produce some genital growth and it is possible that premature stimulation may adversely affect the function of the testis in later life and stimulate premature closure of the epiphyses. After following patients very carefully during the past seven years, our impression is that the treatment is beneficial instead of harmful when

TABLE 2.—Analysis of Our Results in Treatment of Undescended Testes with Chorionic Gonadotropin

Age, Years	No. of Patients	Total No. of Undescended Testes	Total No. Descended	Percentage Descended	Type				Location									
					Bilateral		Unilateral		Intra- Abdominal		Inguinal		Ectopic					
					No. Before Treatment		No. Before Treatment		No. Before Treatment		No. Before Treatment		Deflected Over External Oblique Muscle		Deflected Over Rectus Sheath		Deflected Toward Perineum	
					No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended	No. Descended		
10 mo. to 37 yr.	67	89	21	24	44	10	45	11	34	12	33	17	6	1	0			
10 mo. to 15 yr.	52	65	17	26	26	6	39	11	19	1	23	13	4	1	0			
16 to 37 years.	15	24	4	17	18	4	6	0	15	1	5	4	2	0	0			

The testis normally moves into the scrotum during the ninth month of fetal life. It appears that both hormonal and anatomic factors are involved. It has not been clearly established what these hormonal factors are in intra-uterine life. The presence of large quantities of chorionic gonadotropin in the urine of the pregnant mother and the production of descent with this material after birth suggest that it may play an important role in the descent of the testes in utero. When undescended testes move into the scrotum at the time of puberty without treatment, the stimulus appears to come from the anterior lobe of the pituitary. In descent of the testis it is necessary to consider not only hormonal factors but also the anatomic integrity of the parts involved. According to some observers the gubernaculum plays an important role. Thus absence of scrotal fibers and persistence and overdevelopment of other fibers such as those that are attached to the external oblique, base of the penis and the perineum may account for some abnormal deflections.

STATUS OF GLANDULAR THERAPY

We can see no reason to modify the conclusion previously reached; namely, that chorionic gonadotropin causes descent only of those testes which would descend at the time of puberty without treatment, i. e. those not retained by mechanical factors. Since this appears to be the case, what is the virtue of treatment with chori-

properly carried out. The majority of boys with undescended testes appear to be slightly frail, delicate and somewhat effeminate. With chorionic gonadotropin their appetite improves, their muscles become larger and firmer and they become more vigorous and masculine. However, chorionic gonadotropin is a very potent therapeutic agent and must be used carefully. Its chief danger as we see it is the production of excessive genital growth, which can be avoided if the patients are carefully followed during treatment. Growth of the genitalia stops as soon as the stimulus is withdrawn. The main problem now seems to be how early treatment should be started. Most of the patients that are referred to us are more than 3 years old and the thing that impresses us is that the undescended testes in these patients remain small after being brought into the scrotum either by glandular therapy or by operative procedures. Perhaps the testes were defective in the beginning and perhaps this was the reason for their failure to descend, but it is also possible that the testes were small because they had remained too long in their abnormal environment. Since the normal environment of the testis is the scrotum and since the testis normally moves into the scrotum during the ninth month of fetal life, it is possible that better results would be achieved if treatment was carried out at a much earlier age, perhaps shortly after birth.

3. If there is an associated hernia, operative procedures will be necessary in any case.

The effective dose of chorionic gonadotropin varies from 100 to 500 international units three to six times a week. In successful cases the testis usually descends within eight or nine weeks, although much longer periods of treatment are necessary in some instances. In order to determine whether or not the treatment will be effective, it usually must be continued until some genital growth has been produced. If operative procedures prove necessary, they should be carried out at once. If glandular therapy is discontinued for any length of time beforehand, regression in the size of the genitalia may increase the technical difficulties of the operation.

Pituitary and equine gonadotropin are not very suitable therapeutic agents, although theoretically desirable, because they contain both follicle stimulating and luteinizing factors, whereas chorionic gonadotropin contains principally luteinizing material. In actual practice the pituitary and equine gonadotropins available at present produce little stimulation of the male gonad.

Since chorionic gonadotropin produces its effect by stimulating the testis to produce male sex hormone, it might be considered desirable to administer male sex hormone itself in the treatment of undescended testes. However, this material damages the seminiferous tubules⁴ and should not be used unless both testes are incapable of responding to stimulation.

SUMMARY

The evidence available suggests that there are two causes for failure of descent of the testis:

- (a) A glandular deficiency.
- (b) Anatomic abnormalities.

Since the testis can function normally only in the environment of the scrotum, it is logical to assume that the earlier it is brought into the scrotum the more likely it is to be normal.

With glandular therapy it is possible to determine at an early age whether operative procedures are necessary or not. If there is no mechanical obstruction, the testis will descend with glandular therapy alone. If it does not descend, operative procedures are necessary and are facilitated by the enlargement of the parts produced by glandular therapy.

Chorionic gonadotropin is the most satisfactory therapeutic agent in most instances.

Treatment involves the intelligent combination of glandular therapy and surgical procedures.

The age of the patient and location of the testis have some bearing on the success of glandular therapy. The incidence of successful results is higher before than after the age of puberty.

We were able to produce descent in only 2 of 34 intra-abdominal testes. The majority of the successful results occurred in testes which were in the inguinal canal or outside the canal.

It is still uncertain how early treatment should be carried out, but our observations suggest at a very early age.

It is important to distinguish between true cryptorchism and pseudocryptorchism (migratory testis). Migratory testes descend spontaneously at the time of puberty and require no treatment. Their inclusion in studies of glandular therapy exaggerates the percentage of successful results.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. KUNSTADTER, DR. SHELTON, DR. NOVAK AND DRS. THOMPSON AND HECKEL

DR. THEODORE O. ELTERICH, Pittsburgh: This symposium is important and timely. Faddists, charlatans and well meaning but inadequately informed physicians have beclouded the issue with exaggerated or contradictory statements. Endocrine preparations were injected into adolescent buttocks long before there was any attempt to study the normal anatomic and physiologic deviations of the onset of puberty and the varying characteristics of adolescence. It is a platitude to say that the United States is a racial melting pot, but in no phase of medicine is this statement of greater scientific significance. Certain race mature early. We expect an Italian or a Jewish girl to establish her menarche earlier than a girl of Scandinavian origin. But with the intermarrying of these innumerable races how can we know the limits of normal deviation in their offspring except in grossly abnormal situations? What is true of our lack of knowledge of normal deviations in maturity onset is also true of normal deviations in growth and other phenomena. I will say a few words about the growth abnormalities of puberty. It is not often that one has an identical twin as a control. Marcella and Marie were 13½ years old when I first saw them. Marcella, with a glioma of the optic chiasm, was 36 pounds (16 Kg.) less heavy and 11 inches (28 cm.) shorter than her identical twin, Marie. She had no evidence of secondary sex development. She showed many characteristics of hypothyroidism. Marie, the normal identical twin, had established her menarche and manifested the expected secondary sex characteristics. There are varying causes of precocious puberty. The following cases, which have been under my care for many years, illustrate three different types: Viola began to menstruate at 2 years. When she was first seen by me at 4 years she was in reality adolescent, with all the secondary sex characteristics of a girl of 14 years. Her condition is evidently due to hyperplasia of the basophilic cells of the anterior pituitary. She is now at nearly 15 years a dwarfed adult only 51½ (130 cm.) inches tall, with a pronounced disproportionate shortness of the lower extremities. Irma-Fred is a pseudohermaphrodite, a condition evidently caused by hyperplasia of adrenal cortical tissue. Besides the scrambling of his secondary sex characteristics he is a dwarfed adolescent only 55¾ inches (140 cm.) tall at 19 years. He was born with evidences of precocious puberty and secondary sex characteristics. Johanna illustrates a third type of precocious puberty—virilism. At 5 years she began to mature, but after a masculine fashion. This condition is also due to hyperplasia of adrenal cortical tissue.

DR. E. PERRY McCULLAGH, Cleveland: In commenting on adiposogenital dystrophies I wish to emphasize the importance of accurate diagnosis. We should no longer speak loosely of "pituitary cases" or consider all obesity in adolescence as Fröhlich's syndrome. In such cases the possibility of suprasellar cyst should be remembered and this possibility eliminated by roentgenograms and perimetric fields if indicated. In the fat child who is taller than normal a diagnosis of Fröhlich's syndrome should be considered doubtful, as the increased skeletal size argues strongly against hypopituitarism. Thyroid feeding of such children may cause abnormal increases in skeletal growth. Hypothyroidism is frequently assumed on the basis of obesity plus perhaps a coexisting hypometabolism. In both instances the assumption is usually unsound. Hypothyroidism may be concomitant in some cases but should be diagnosed on the basis of such criteria as those which Dr. Shelton has so accurately outlined for us. Assays of limited diagnostic value. If the diagnosis is doubtful for children during adolescence the finding of normal adult levels of androgens or estrogens in the urine may deter us from unnecessary treatment. Thyroid is of limited value in treating obesity. It is well to remember that the basal metabolic rate is not likely to be raised more than 10 or 15 per cent by the doses of thyroid which can be used, and, accordingly, the change in the caloric requirement is likely not to be greater than 150 or 200 calories a day. In my practice, I commonly use a diet based on the basal caloric requirement for the ideal weight, adding 10 per cent. I have used pituitary metabolic hormone in a few cases, but it

in which surgery is imperative from those in which it is contra-indicated?" One of my main theses has been that we have not recognized instances of hyperthyroidism other than those that occurred in cases of exophthalmic goiter. Furthermore, the use of the term "hyperthyroidism" in children is misleading. If they have hyperactivity it is due to exophthalmic goiter, but we can recognize as clinical evidence overactivity of the gland, such as one sees in older patients. I think that answers both parts of that question. The last question is "Do you imply that all children with so-called exophthalmic goiter have actual exophthalmos as determined by measurement by exophthalmometer?" I can state that exophthalmos sufficient to be measured by the instrument occurred in about 90 per cent of the cases. In about 10 per cent it was very slight and in a few instances not evident. Other symptoms complete the picture, and identification of the type of pathologic change in the thyroid gland established the diagnosis of exophthalmic goiter.

Dr. A. WILMOT JACOBSEN, Buffalo: I have a question: "Is there any evidence that Lorain and Brissaud dwarfism are due to endocrine dysfunction or hypofunction?" This question refers to the delicately built, normally proportioned dwarfs who are made sexually infantile, and this condition, theoretically, should be due to primary pituitary deficiency, and therefore I feel that they should be given a trial on appropriate endocrine therapy. The next one is "Is there any hormone or hormones for anti growth effect for those who grow too tall when height alone is excessive?" Several things have been suggested. One is irradiation of the pituitary to try to decrease the output of growth hormone, but the chance of damage to other important hormones of the pituitary is too great for such a course to be advocated. Another theoretical suggestion has been to try to close the epiphyses by giving an excess of the sex hormone and, as we have heard today, that does not seem to be a highly satisfactory way to treat this condition. It is a question whether it really does just that. I believe that at present we have no adequate way to treat these excessively tall children.

Dr. EMIL NOVAK, Baltimore: I have quite a sheaf of questions, but I think I can group them fairly satisfactorily. First, with reference to Dr. Turner's comment on prepubertal obesity, the traditional distinction between exogenous and endogenous factors is still a useful one. Many children, like many adults, are fat because they overeat and do not exercise sufficiently. Correction of these faults brings about disappearance of the excess weight. On the other hand, I am convinced that the endocrine "reshuffle" of puberty exercises a beneficent effect in many of the more moderate degrees of endocrinopathic prepubertal obesity, while in other cases the adiposity is progressive and may even be accentuated by puberty. In the common so-called pituitary type, menstruation and ovulation may both be affected, but they are frequently entirely normal in that large group of cases in which the disturbance is believed to be in the hypothalamus rather than in any of the endocrine glands. Many of the most extreme cases fall into this group, as exemplified by many of the fat women of the circus. Three of the questions submitted to me deal with the indications for gynecologic consultation in the adolescent girl. First of all it should be emphasized that the least important part of gynecologic consultation in patients of this age group is apt to be the examination of the pelvic organs. More important is the study of the general and endocrine status and the mode of life as to such things as exercise and diet. It is some abnormality of menstruation which most frequently brings such patients to the gynecologist, and the intelligent study of these disorders compels him to broaden his horizon far beyond the brim of the pelvis. In a large proportion of cases reassurance and education of the child and her parents is far more necessary and effective than is endocrine therapy. This applies particularly to the "shots" to which so many practitioners resort for the irregularities so common at this age. Many of the latter, such as periods of amenorrhea or menstrual arrhythmia in the first few years of menstrual life, often adjust themselves spontaneously. In reply to another question, I may again emphasize that endocrine therapy, except for the cautious use of thyroid in many cases, is rarely called for in the management of primary amenorrhea in girls under 17 unless a very definite endocrinopathy is demonstrable. Another query has to deal with a possible causal

influence of amenorrhea in schizophrenia. For this there is, so far as I know, not the slightest evidence. On the other hand, it is a well known fact that amenorrhea is a frequent finding in the various forms of insanity.

DR. RALPH H. KUNSTADTER, Chicago: The question is raised "When to treat adiposogenital dystrophies, in view of the fact that many of them recover spontaneously with the advent of puberty?" I think this depends principally on two factors. These are the physical condition of the child and the psychologic reaction. A child who is tremendously obese, knock kneed and flat footed and has a typically feminine appearance needs medical treatment. Nobody can predict when puberty is going to take place. It is supposed to occur in the male somewhere between 12 and 16 years of age. When the child is physically handicapped because of his appearance, I don't think we are justified in waiting for spontaneous improvement with puberty. I agree with Dr. Turner that many of these obese children do not improve spontaneously. As I showed in the case of the two brothers, obesity was tremendous even after puberty and adolescence occurred. If the child has a physical appearance that definitely makes him different from the normal type of child at the age when puberty is supposed to take place, he should be treated. The psychologic factor is particularly important in children who are starting in high school and are physically handicapped because of their appearance. They are frequently self conscious, particularly when they go into the swimming pools, into the gymnasiums and to social gatherings. At the present time there is criticism with regard to diagnosis of adiposogenital dystrophy from those who feel that many of these patients are simply children who overeat and will outgrow their condition if they have proper psychologic treatment and nothing more. The question of appetite is an involved subject. Meyerson has shown that overeating may be a question of some psychologic disturbance, an outlet for some emotion, particularly in women and children. They eat constantly because they haven't anything else to do or because they are disturbed or frustrated. There are also organic factors to be considered, particularly since we know that the hypothalamus is associated with appetite. Adiposogenital dystrophy may be produced by definite lesions in the hypothalamus. We now know, for example, that the pituitary itself may liberate increased or decreased amounts of sex hormone, depending on whether there is stimulation of the posterior or anterior portion of the hypothalamus. There is reason to believe that the hypothalamus is the controlling mechanism of the endocrine system, and not the pituitary.

DR. WILLARD O. THOMPSON, Chicago: Dr. McCullagh asked whether there was any danger of cryptorchism lasting until the age of 10 years or even until the age of puberty. What is the harm of waiting until then? We pointed out that the normal environment of the testis is the scrotum, and it cannot function normally except in the environment of the scrotum. The testis normally moves into the scrotum during the ninth month of fetal life. We previously thought treatment should begin at the age of about 3 years. In many instances in which the testis had descended with chorionic gonadotropin or as a result of surgical procedure carried out after unsuccessful treatment with chorionic gonadotropin we have observed that the testis, even some time after it has come down, is smaller than the testis which was originally in the scrotum and is sometimes flabby as well. In other words, in spite of being brought down it is somewhat abnormal. We are therefore beginning to wonder whether the reason for this abnormality is the fact that we did not carry out the treatment early enough, and we are beginning to revise our age for treatment downward. "Is there any danger of malignancy, or is the danger of malignancy reduced by treatment?" We do not think so. If the testis is going to develop a malignant tumor, we think it will do so whether it is in the abdomen or in the scrotum. Furthermore, we should like to point out that the danger of undescended testes becoming malignant has been greatly exaggerated. We have not seen a single instance of malignancy in all the patients with cryptorchism whom we have followed. Dr. Turner asked me to say more about the influence of the male sex hormone on growth. We have observed that growth of the skeleton in young boys and in certain dwarfs may be stimulated either by administering

chorionic gonadotropin, which stimulates the production of male sex hormones, or by administering the male sex hormone itself. "If this is so," Dr. Turner says, "why do eunuchoid individuals grow so well? Why are they sometimes even taller than the average?" That is a very good question, which nobody can answer at present. With glandular therapy we can determine at an early age whether the testis is retained by mechanical factors or whether it is not, and if it is retained by mechanical factors we can, as a result of the growth produced by glandular therapy, carry out operative procedures just as easy in a very young child as we can in the same patient without glandular therapy at the age of 12 or 14 years. It is very important that there should be no interval between the time at which glandular therapy is stopped and that at which the surgical procedure is carried out, because, if there is, some regression in size may occur which makes the operative procedures more difficult.

A PLEA FOR UNITY IN HEALTH ADMINISTRATION AT THE STATE LEVEL

JOSEPH W. MOUNTIN, M.D.

Assistant Surgeon General, Domestic Quarantine Division, United States Public Health Service

WASHINGTON, D. C.

If instead of writing a paper designed for a scientific group I were giving a sermon, I could think of no better text than item 1 from the platform of the American Medical Association as published in a number of issues of THE JOURNAL last year:

The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

Again, if this were a sermon, in adapting the text to my purposes I should need only to substitute the word state for federal. For this resolution seems to me an excellent one to apply to the agencies conducting affairs of public health within the states even as it was to apply within the structure of the federal government.

One may be inclined to qualify my use of "was" in respect to federal reorganization, but I think it is the correct tense for the situation if used without the implication that perfection has been reached. Unity of organization in the promotion of health gradually has been coming to pass at the federal level, though the form is perhaps not precisely that which the Association has been urging for many years. The establishment of the Federal Security Agency two years back brought a number of units which carry on some health activities into one general fold. At the present writing it includes these agencies: U. S. Public Health Service, Social Security Board, Civilian Conservation Corps, Food and Drug Administration, Office of Education, Freedmen's and St. Elizabeth's hospitals, American Printing House for the Blind (Louisville, Ky.), Howard University, Columbia Institution for the Deaf and the National Youth Administration.

The United States Public Health Service is concerned solely with matters pertaining to human health. It is charged with direct administrative responsibility for certain duties. To other activities it contributes technical direction. When occasion demands, as occasion regularly does, the Service acts in an advisory capacity to federal agencies which must maintain a program of health as part of their own operations. Two medical officers, for example, are assigned to the

From the Division of Domestic Quarantine.

National Youth Administration to guide the development of certain medical services which are an integral part of the responsibility of this agency to its beneficiaries.

Though the Federal Security Agency may seem rather loosely knit from a medical point of view, the intent of item 1 of the platform of the American Medical Association is being carried out in an evolutionary way.

My plea for the application of this principle to state agencies does not imply too close an analogy between the structure for public health within the federal and within the state governments. The state agencies differ from those at the federal level chiefly in that they carry direct responsibility for the administration of service programs. It is precisely in this departure that one recognizes the even greater need for unity of organization. For it is particularly among operating agencies of service that aims and duties are apt to overlap and underlap and sometimes collide, and a likely corollary to the confusion is great waste of effort, energy and of course money. The zealot for good public health administration would find the health structure of the states a rich field in which to exercise his ardor.

The United States Public Health Service has on hand some recent, exact data on this confusion of effort, which were gathered for a revision of Public Health Bulletin 184,¹ the descendant of the survey of state health organizations published by the American Medical Association in 1915.² The current revision will be a new version. Not only have the previous data, as is the way of all data, grown old and inadequate, but the public health scene has undergone a great transformation. Health departments today are participating in programs which had not been developed as recently as ten years ago. Either the technics were inadequate or the activities were considered outside the bounds of public health administration.

Furthermore, the emphasis was shifted somewhat in planning the forthcoming revision. The other bulletins amounted to a study of the divisions of state health departments, and the approach in gathering the data might be summed up by the question "What does this division do?" Such a study gives a picture of a division at work. In the latest survey the approach could be characterized by the questions "What branches of this state government are responsible for the work in (for instance) tuberculosis?" and "What is the total program?" The answers add up to the current story for each field of activity in terms of which agencies are operating there and what they are doing. On that emphasis hangs this tale of duplication and lost motion.

The survey schedule included all the old line public health fields, such as vital statistics; acute communicable disease control; maternal and child health; control of tuberculosis, including hospitalization; sanitation of food, milk and water supplies, and sewage disposal.

Other activities in the schedule included some not commonly undertaken in public health programs. Social thought in the last ten years has been busily coordinating considerations of personal health, economic security and happiness. The conclusions reached are by no means hard and fast. But the present survey

has been conditioned far more than the others were by considerations of what in the light of present knowledge should go into the efforts to promote the public's health.

A program such as that for the control of the venereal diseases represents a combination of the old and the new aims. Syphilis is a communicable disease, but it is a clinical entity as well, and the programs recognize both these facts. Society is to be protected. The individual is to receive the diagnosis and treatment that will rid him of his disease.

The schedule as set up does not define public health as a program of any particular content. Care was taken to avoid having it do just that. Also, the purpose of an activity was not decided according to where the administrative responsibility had been placed. The inclusion or exclusion of an item was decided by whether the item was usually defended before appropriating bodies on the basis of its influence on human health and well-being.

Each function was traced in all its ramifications through the entire structure of state government, irrespective of where administrative responsibility had been placed. The infant hygiene program, for example, would usually be found in the health department, but the supervision of institutions for the care of children, a vital part of any program of infant hygiene, might be vested in the department of welfare.

As far as possible, under each major category of service were listed the several participating state agencies. Participation was accounted for under five headings: regulation, promotion and education, supervision and advice, financial aid to local units and operation of direct service programs.

This list is a generalization for the nation as a whole. A state may use one or any combination of the approaches in it, in a complete health program or a partial one and through an astonishing multiplicity of agencies. In other words, no uniform pattern as to organization or program exists throughout this country.

In one state the activities relating to health are in the hands of no less than eighteen separate agencies. The smallest number of agencies involved in any one state is six. The median number of departments, boards and commissions is eleven per state.

Haphazard is the word for the situation. An artist given to surrealism would be best equipped to present a picture of the haphazardness in all its glowing complexity, but both talent and time restrict me to a word picture of a few activities and the agencies that father them.

In general, the states vary most in their ideas as to the portion of responsibility to be borne by the state agency and the portion to be delegated to local jurisdictions. One state may cleave entirely to advisory, supervisory and promotional activities. Another may be active in programs of direct service, such as those which involve treatment for the venereal diseases or roentgenograms of the chest. Or a state may hold some programs to the advisory function and consider others of value only if they carry direct services. One state may grant financial aid for activities far different from the ones selected for this type of assistance by its neighbor.

The administration of tuberculosis control programs offers an interesting case study of the variety that is the spice of life under some circumstances but a drawback to life when practiced by the agencies that should be working with all possible precision to promote health.

2. Chapin, C. V.: *A Report of State Public Health Work, Based on a Survey of State Boards of Health*, Chicago, American Medical Association, 1915.

Contact B was a school contact of patients 3 and 4 and also attended the school picnic on June 6. This boy lived with his mother in La Grange. The father (patient 11) of this child was separated from the mother and lived in Berwyn, 4.9 miles from La Grange. The child visited with his father on June 7, 14, 19, 21 and July 2, during which time they swam, ate and attended the theater together. From June 21 to July 2 the boy had an active smallpox revaccination that confined him to his home. On July 5 the father became ill with an ascending paralytic poliomyelitis, which terminated in respiratory paralysis and death on July 9. Examination of the brain and cord revealed extensive and profound histopathologic changes characteristic of severe poliomyelitis. The son (contact B) left the state and could not be located until the first part of August, at which time a stool specimen was obtained from which the virus of poliomyelitis was subsequently isolated. An additional noteworthy fact is that patient 11 worked in a large administrative office in Chicago and some of his associates lived in Western Springs and Oak Park. The father of patient 10, who contracted poliomyelitis on July 3, was also a worker in this office but it was

year old sister (patient 6) became ill with poliomyelitis on June 26.

Contact D on June 27 drank some of the lemonade remaining after the closure of the stand on June 26. On June 30 this boy had his adenoids removed for the second time. He returned from the hospital the following day and remained indoors until July 4. He later stated that during this period his joints and back ached and at times he felt dizzy. He also said that once he saw double. However, there was no history of fever, headache, stiff neck or stiff back. On July 4 he attended the aforementioned village celebration, at which time he was in contact with patient 12. His 23 year old sister (patient 15) became ill with poliomyelitis on July 11. The stool specimen collected from contact D was subsequently shown to contain the virus of poliomyelitis.

Patients 2, 3 and 4 lived in La Grange Park. Patients 1, 6 and 9 lived in La Grange. Patient 9, a Negro boy,

was the son of a mail carrier whose route was in La Grange. There was no other detectable contact between this patient and other patients in this vicinity. Patients 5, 7, 12, 14 and 15 lived in Western Springs. Patients 8 and 13 lived in Park Ridge approximately 12 miles away from the aforementioned areas, and no contact could be traced between the Park Ridge patients and the others.

The epidemiologic survey disclosed three separate sources of drinking water, nine different milk supplies and attendance at ten different schools. Five of the patients swam in four different swimming pools. A trained physical therapist made a complete muscle examination of all the contacts to the patients involved in this study with the thought that there may have been some mild unrecognized cases. No muscle weakness or paralysis was found among these contacts.

When it was ascertained that funds would be available for laboratory study of this outbreak, the prompt collection of stool specimens was started. The laboratory study was restricted to the four contacts A, B, C and D, the 5 Western Springs patients 5, 6, 12, 14 and 15 and family, playmate, lemonade stand (lemonade drinkers only) and indirect or casual contacts of these patients. The number and type of stools collected and the results to date are presented in table 2. For control

Geographic distribution of cases.

25 residents of Western Springs who were of the same age group as the patients and who had no known contact with the patients or their contacts submitted stool specimens for study. Five of the control group had attacks of diarrhea during the time of this outbreak.

METHOD OF COLLECTION, PREPARATION AND INOCULATION OF STOOL SPECIMENS

The stool specimens, weighing about 45 Gm. each, were collected in sterile glass jars and refrigerated in an insulated box until delivered to the laboratory, usually within twelve hours. In the laboratory they were kept at approximately 8 C. for twenty-four hours and then frozen in the freezing compartment of an electric refrigerator or with solid carbon dioxide. They were maintained in the frozen state until prepared for inoculation.

Rhesus monkeys (*Macaca mulatta*) were inoculated by the combined intranasal and intraperitoneal routes. Untreated feces, diluted with sterile distilled water from 1:2 to 1:20, depending on their consistency (on the

the 6 contacts from whom virus was isolated were in the group around the lemonade stand and includes contact D. One, contact B, was in contact with patients 3 and 4 before and at the school picnic, and the sixth was a playmate contact of patient 5.

The primary virus isolations were confirmed by histopathologic findings and by monkey passage in 4 of the contacts. Guinea pigs and mice inoculated with this material remained asymptomatic. Confirmation studies on the remaining two virus isolations from contacts are in progress.

Fourteen control stool specimens have been inoculated up to the present time. Although some of the monkeys exhibited high temperatures after short incubation periods, there was no evidence of paralysis in any of the monkeys inoculated with the control specimens. The cause of this atypical febrile reaction is being investigated.

As indicated in table 2, we have yet to study the feces from 1 case, 10 contacts and 11 controls. We are also studying the persistence of the virus in the stools of cases and contacts.

SUMMARY

A combined clinical, epidemiologic and laboratory study of a suburban outbreak of poliomyelitis has been partially completed. Typical clinical findings in the cases and demonstration of the specific pathology of the disease in one of the fatal cases, and isolation of the poliomyelitis virus from the feces of patients proved it to be an outbreak of poliomyelitis.

The virus of poliomyelitis was isolated from the feces of 3 of 4 patients collected about one month after the onset of symptoms.

The virus was found in the stools of 6¹ of 38 contacts; on the other hand, there has been failure to isolate the virus from 14 control specimens of feces from normal residents in the community.

Virus was found in the stools of two presumably healthy children who were in contact with adult members of their families who became ill with poliomyelitis.

Virus has been isolated from a presumably healthy person two months after his contact with persons who became ill with poliomyelitis and one month after contact with his father, who died of poliomyelitis.

737 South Wolcott Avenue.

What Is Medical Research?—Mere recording of observations and reading the dials of complicated instruments of precision is not research. Becoming acquainted with all the doctrines, axioms and concepts in a particular field is not research, though it may well precede research. Summarizing or compiling facts is not research. A research man must know his data and how they were obtained. The mere compiler can be ignorant of his material. Such records, without a hypothesis to explain the cause or correlation of some element or aspect they present, and a fresh test of that theory, are merely records. Long study is not research; study alone is passive. It may be swallowing but it is not digestion. Rationalizing and contemplating lack the confirmation secured by testing the proposed explanation. Analysis is a valued element of research method but it is not all there is to research. . . . Another confusion lies in mistaking the result for the cause. Research may lead to invention, or invention may call for research, but invention is not research. Indeed, medical research is often handicapped if it is pressed to be immediately applicable. This is rarely understood by the outside. Research is the response to curiosity, not to need.—Gregg, Alan: *The Futherance of Medical Research*. New Haven, Conn., Yale University Press, 1941.

GASOLINE INTOXICATION

WILLARD MACHLE, M.D.

CINCINNATI

Although poisoning by petroleum distillates has been a recognized clinical condition ever since these products began to find commercial use, few cases have been reported, probably because they are of sporadic occurrence and in cases of mild acute poisoning recovery is usually prompt and complete. Opportunities for harmful exposure are frequent however, and, as gasoline has become a material essential in daily life and its distribution is constantly increasing, intoxication by gasoline will doubtless become more, rather than less, frequent.

The monthly consumption of gasoline in the United States increased from about 1,000,000,000 gallons in 1927 to more than 2,000,000,000 gallons in 1940,¹ and this was due almost entirely to its increased use as a motor fuel. As a result, the persons having a possible exposure to gasoline include greater numbers of motorists and also greater numbers of men employed in its production, distribution and marketing. The number of gasoline service stations has more than doubled in the past fifteen years; there were 226,000 in 1938, and about 100,000 new pumps are put into service each year. Furthermore, the expansion of the motorized divisions and the aviation branch of the armed forces has led and will continue to lead to increasing handling and use of gasoline, under conditions somewhat less than ideal, in certain instances, from the point of view of safety.

THE AGENT

Gasoline is a mixture of petroleum hydrocarbons having a distillation range of from less than 100 to about 400 F. Its composition varies with its source and is never completely known, but in general there are four groups of components—paraffins, olefins, naphthenes and aromatics. Straight run gasoline made from petroleum produced in the United States is principally paraffinic in character and may contain more than 65 per cent of paraffin hydrocarbons. Several crude oils in the western part of the United States, however, yield straight run gasolines which are much more aromatic or naphthenic in character than the general type of fuel, although the total content of aromatic hydrocarbons in these gasolines will probably not exceed 10 per cent. Many foreign crude oils do yield highly aromatic gasolines, notably Borneo petroleum, in which nearly 40 per cent of aromatic hydrocarbons are present in the gasoline fraction. These aromatic hydrocarbons are principally benzene, toluene and the xylenes. All straight run gasolines contain naphthene hydrocarbons in varying proportions, but the content of olefin hydrocarbons is negligible.

The type of chemical compounds present in a gasoline also depends on the way in which it has been made. Vapor-phase cracked gasoline, for example, is highly unsaturated and quite reactive chemically because it contains from 50 to 75 per cent of olefin hydrocarbons. The rest of these gasolines are composed principally of

¹From the Kettering Laboratory of Applied Physiology, University of Cincinnati College of Medicine.

1. Hubner, W. H., Refinery Technology Division, Ethyl Gasoline Corporation: Personal communication to the author.

aromatic and naphthenic hydrocarbons, there being practically no paraffins present. With improved methods of manufacture designed to give a greater yield, there has been a change in the type of gasoline marketed. In 1925 two thirds of the total production was straight run and natural, consisting mainly of paraffinic hydrocarbons, types which today make up only about 40 per cent of the total, while cracked, reformed or polymerized gasolines, all with a high olefin and aromatic content, make up the remaining 60 per cent.²

The physiologic response to the various compounds in and fractions of gasoline varies widely.³ The unsaturated compounds, especially the aromatics, have definite convulsant effects, while in general the irritant and toxic effects of a given series of like compounds increase with increase in molecular weight.

Two other changes, noteworthy from a toxicologic point of view, have been made in the past fifteen years: both the vapor pressure and the volatility have increased slightly. The 10 per cent point of winter gasoline (160 F. in 1925) was only 125 F. in 1940,¹ and from the standpoint of health hazards this increased volatility is of considerable significance.

Although it is known that the hydrocarbon content of gasoline is the portion that causes poisoning, questions have been raised concerning certain agents which are added to gasoline to increase its effectiveness, particularly tetraethyl lead. This has been used in gasoline continuously since 1926 in concentrations not exceeding (for motor fuel) 1 to 1,260 by volume. Investigations and reports over a span of years have demonstrated that lead poisoning will not result from the use of leaded gasoline as it is usually handled in commerce.⁴ The hazard is limited to the manufacture of the tetraethyl lead and the antiknock mixtures, the mixing of these materials with gasoline and the cleaning of tanks in which leaded gasoline has been stored. Numerous reports of lead poisoning caused by the handling of motor fuel containing tetraethyl lead have been brought to my attention, and several published articles have considered this possibility, but in every instance careful investigation has established that plumbism was not a factor in the production of illness.

A number of materials, usually phenolic compounds, particularly polyhydroxy and amino phenols, are often added to gasoline to prevent oxidation during storage and to delay formation of gum.¹ Because of their low vapor pressures and the low concentrations employed (0.001-0.002 per cent), they have no hygienic significance. This is true also of other adjuvants sometimes added to gasoline such as lubricating oils, colloidal graphite and lecithin.

ETIOLOGY

Gasoline intoxication occurs with considerable frequency outside the petroleum industry;⁵ substitution of gasoline for solvents, its industrial use and careless handling are chiefly responsible. Severe chronic gasoline poisoning has occurred in dry cleaning plants; the pressing of clothes still damp with gasoline is dangerous because high temperatures volatilize the more toxic, heavier fractions, and the toxicity is said to be likewise increased.⁶

Gasoline is sometimes ingested accidentally, usually by children but also by motorists attempting to siphon it from tanks. Water from wells contaminated by gaso-

line is an infrequent source of poisoning. The single oral dose usually fatal to man is approximately 7.5 Gm. per kilogram, but death has been caused by as little as 10 Gm.⁷ and recovery has followed the ingestion of 250 Gm.⁸ This divergence may be due in part to the wide variability in the chemical composition of gasoline; it is absorbed more quickly if it contains a high concentration of benzene and other aromatic hydrocarbons, since the solubility product of benzene in blood, like the coefficient of water solubility, is from three to four times as great as that of natural gasoline.⁹ Other factors are also of importance, however. In the most serious of Nunn and Martin's cases,¹⁰ some of which were fatal, there was evidence that liquid had been aspirated. Emesis and the time interval between the ingestion and its occurrence are also of great importance, since they influence the effective dose retained. Individual susceptibility and the presence of food and fats in the stomach, tending to delay absorption, must be considered. It is probable that some habituation occurs on repeated ingestion. Schwarz's¹¹ patient drank from 3 to 5 cc. of gasoline once or twice daily for from five to six weeks and recovered from the effects.

There is no conclusive evidence that systemic poisoning from gasoline can be produced in man by cutaneous absorption alone. In Lassar's case¹² gasoline was applied to the skin as a remedy for scabies, and death followed in two days, but inhalation probably played a role. Friedeberg¹³ states that sufficient gasoline can be absorbed through the skin to cause intoxication, but from my own observations the hazard from cutaneous absorption in man would seem to be slight indeed and of little practical importance when compared with the exposure to vapor that usually coexists. Lasareff's experiments¹⁴ indicate that definite absorption occurs through the skin of rabbits.

The usual mode of absorption of gasoline is through the respiratory tract. As in the case of other volatile materials, if the concentration of gasoline vapor in air is high, absorption through the lungs may be extremely rapid and symptoms may appear after a few minutes of exposure. There is no agreement as to the amounts necessary to cause intoxication. The Massachusetts code¹⁵ sets the maximum allowable concentration at 1,000 parts per million (4.5 mg. per liter), and this is close to the figure given by Fieldner.¹⁶ We feel, however, that it may be too high for continuous work. Susceptible persons may show symptoms after exposure

to concentrations as low as 300 to 500 parts per million, for example the functional neuroses in rubber workers reported by Vigdortschik¹⁷ following exposure to concentrations of 110 to 450 parts per million. In Fieldner's test, men exposed to 1,000 parts per million showed drowsiness, dulness and numbness at the end of fifteen minutes and vertigo, ataxia and slight nausea as well at the end of an hour. Symptoms appeared much more quickly with exposures to 3,000 parts per million, and with exposure to 7,000 parts per million there was definite intoxication in five minutes.

Few data are available on the amounts of gasoline vapor in air that will cause death in man in a short period of exposure, but amounts in excess of 10,000 parts per million are rapidly fatal for most experimental animals. Since gasoline vapor is heavier than air, concentrations far in excess of these may readily occur if gasoline is decanted or exposed to air in enclosed places and concentrations rapidly fatal to man may be formed. Moreover, in tanks, excavations and other poorly ventilated enclosures the displacement of air by the heavier vapors adds the further hazard of asphyxia.

Susceptibility to gasoline vapor varies greatly, and habituation is a usual phenomenon, as we learned in a study of men engaged in filling barrels with gasoline in a poorly ventilated location.¹⁸ The reason is not understood. Experiments attempting to relate habituation to changes in the blood lipids have given conflicting results.¹⁹ Since gasoline is apparently not oxidized or broken down to any significant degree in the body (excretion is mainly by way of the lungs), this question must remain unanswered for the present.

PATHOLOGY

The pathologic changes caused by gasoline are dependent on both its irritant action and its lipolytic activity. There is no characteristic general morbid anatomy, but study of reports²⁰ reveals almost uniformly damage to the lungs manifested by hyperemia, petechial hemorrhages, subpleural extravasations and, in some cases, gross pulmonary hemorrhages which may involve the entire lobules, with the alveoli filled and the epithelium necrotic. Bronchitis is frequent. Pleural effusion was an outstanding finding in 1 case reported by Johnstone.²¹ Some degree of pneumonitis is usually present, especially if the gasoline has been ingested and aspiration has occurred, or simply as the result of its excretion by the lungs. Although as a rule most pronounced in the lungs, damage to the vascular endothelium is seen in many tissues, such as subserous

hemorrhages in the liver, kidney and spleen and hemorrhages into the serous cavities in animal experiments. In addition, there is evidence of general damage to the parenchymatous organs. The liver may be enlarged and show cloudy swelling, usually centrilobular, and there may be fatty changes. In the kidney, edema may be considerable; damage is mainly in the proximal convoluted tubules and the glomeruli, where lipid degenerative changes are seen, with deposits of albuminous material within the glomerular spaces.

Few studies of the nervous system in acute poisoning have been reported, and the changes described are not specific. Hyperemia and edema of the brain and meninges are usually present, and perivascular extravasations occur here as elsewhere. Myelin swelling is usual, and, in 1 case²² in which peripheral neuritis had resulted from the poisoning, part of the fibers were partially denuded of myelin, with gross swelling of the nerves.

As in any acute general intoxication, the types and degree of pathologic change are influenced by the interval between ingestion or exposure and death. If death occurs within a few minutes or hours, few changes may be seen other than edema of the lungs and central nervous system and congestion and scattered hemorrhages, especially in the lungs. If days or weeks elapse, one sees in addition variable degrees of necrosis in the lungs, cellular reaction, fibrin deposits, blood pigment and regenerative changes in the liver and kidneys.

In chronic poisoning the anatomic changes are neither pronounced nor specific. Following ingestion, dilatation of the stomach is usual, as well as hyperemia and edema of the enteric mucosa. Submucosal and interstitial hemorrhages may be present. Hepatic and renal sclerosis were reported in 1 case of chronic involvement.²³

SYMPTOMS AND SIGNS

Acute Intoxication.—Acute poisoning is characterized by severe symptoms in the central nervous system. When exposure is to very high concentrations of gasoline vapor in air, such as may occur in tanks, the victim falls to the ground in a comatose state and may die at once or within a few hours without regaining consciousness. When death is somewhat delayed, the onset of coma may be less rapid and the acute anesthetic action of the gasoline may cause initial symptoms like those of acute alcoholic intoxication: a brief period of incoordination, restlessness and great excitement, with combativeness and swearing, mental confusion, disorientation, ataxia and possibly disturbances of speech and of swallowing. Delirium follows, and coma, which may last for a few hours to several days. The type of coma seems to be dependent to a considerable degree on the chemical nature of the gasoline. In general, paraffin hydrocarbons produce a relatively quiet coma, as has been demonstrated by animal experimentation. Unsaturated hydrocarbons, particularly the aromatic series, cause convulsions, motor unrest, tremors and motor disturbance. Extreme jactitation has been noted frequently, particularly in the animal experiments of Haggard,²³ and muscular twitching is common. Meningismus may be present. In severe

cases epileptiform convulsions are frequent, and they may continue for some time after the coma has passed.

The pulse shows variable changes. Usually weak and rapid in the early stages of coma, it is often full in the presence of considerable motor unrest; bradycardia was noted in several cases, however, and was attributed to stimulation of the vagus nuclei. In general the pulse returns slowly to normal with recovery. A peripheral vasomotor paralysis or acrocyanosis is frequently found and is apparently the result of direct action of the agent on the vessels, since drug response is abolished.²⁴ The temperature is usually subnormal but a rise in temperature of 1 to 2 degrees is seen occasionally, and in very sick patients and in terminal states it has reached 106 F. Respirations are usually shallow and rapid, particularly if poisoning has been by ingestion with some aspiration. Irregularity of respiration is common, particularly in children, and sudden apnea may occur when the patient seems to be doing well.¹⁰

In quiet coma the superficial and deep reflexes are absent or extremely weak, but with jactitation and convulsions, meningismus and violent motor unrest they may be greatly increased, almost to the point of clonus. Unilateral and bilateral reversal of the plantar reflex may be seen. The disks are usually pale. The pupils are dilated, as a rule, and may be unequal. Often they are fixed, and varying degrees of nystagmus may be present. Conjugate deviation has been noted frequently, as has strabismus. Other cerebellar symptoms may be prominent, and there may be *asynergia* and *adiadokocinesis*. Vomiting and singultus sometimes occur during coma and may persist long after.

In cases of subacute involvement in which symptoms may not appear for several hours there are various premonitory symptoms: headache, usually described simply as a feeling of pressure over the head, blurred vision, vertigo, ataxia, tinnitus, nausea and anorexia, weakness and in some cases general abdominal pain. With these symptoms there develops a state of intoxication like that produced by alcohol, known as "naphtha jag." The sensation may be pleasurable and persons have been known to inhale gasoline vapors intentionally, but for the most part the patient becomes quarrelsome and combative, swears violently and evinces a poorly controlled behavior.

Whether or not this prodromal period is followed by more serious symptoms depends on two factors: the duration of the exposure and its constancy. Because of the low solubility of hydrocarbon vapor in blood, exposure must continue for some minutes to bring about conditions of equilibrium and maximum effect.

Under most conditions of exposure in the ranges that cause subacute poisoning, the concentrations are not constant but vary within rather wide limits, and any sudden great increase in concentration will be quickly followed by more severe symptoms.

If poisoning has been by ingestion, with no aspiration of the gasoline, symptoms develop more slowly than in poisoning by inhalation, because of the slow rate of absorption of the agent from the intestine.

Chronic Intoxication.—This term is applied to poisoning which results from exposure to low concentrations of gasoline vapor for long periods of time; severe acute

symptoms do not appear, but minor symptoms of a general nature are manifested a few weeks or months after the exposure has started and become progressively worse. The patient may become disabled in a month or in several years.

Considerable difference of opinion exists as to the incidence of chronic gasoline intoxication. Hamilton²⁵ states that chronic naphtha poisoning is probably common. Our experience indicates that it is rare. We have had more than 2,300 refinery workers under observation, in some instances for as long as ten to twelve years, and have found no signs of chronic gasoline poisoning in any case.¹⁸ Most of these men were employed for brief periods of time, usually not more than a few hours a week, in mixing ethyl fluid with gasoline and for the remainder of their time in all types of refinery work entailing gasoline exposures of all types and degrees of severity. Negative results, in respect to signs of chronic gasoline intoxication, were also obtained in studies of large numbers of filling station attendants, tank wagon drivers and garage mechanics.

On the other hand, in a group of barrel fillers, exposed to concentrations of gasoline vapor tolerable only to habituated persons, we found undernutrition and pallor and significantly low values for hemoglobin and erythrocytes in a high proportion of the subjects. There were frequent complaints of anorexia, nausea and nervousness, and these symptoms were usually related either to a return to work following an interval of freedom from exposure or to brief periods of increased exposure. The condition of these men may be considered one of chronic intoxication or the result of repeated subacute episodes with injury cumulative to a degree.

The clinical manifestations in chronic gasoline intoxication are usually reported to be vague and not characteristic. In Spencer's study²⁶ of 22 persons exposed to gasoline vapors from coupon-canceling machines, the principal symptoms noted were headaches, vertigo, drowsiness, conjunctival irritation with lacrimation, excitability and mild nervous symptoms. A high incidence of dispensary attendance, also noted, might not have been significant had it not been lowered to control levels after kerosene was substituted for gasoline in the operation.

The first symptoms to appear in chronic intoxication are those of a general nature or psychasthenic and neurasthenic manifestations, and they are followed by muscular weakness and cramps, listlessness and a feeling of dullness, fatigue and loss of weight. This loss may reach high proportions: for example, Hayhurst's²⁷ patients lost from 10 to 60 per cent of their body weight over a period of months. Irritative properties of the vapor usually cause conjunctivitis with lacrimation and cough with expectoration. Pulmonary hemorrhage has been reported²⁸ but is uncommon.

Symptoms on the part of the central nervous system occur in wide variety and degree. They may be listed

as follows: mental confusion, loss of memory, a sense of impaired mental faculties, depression, irritability and nervousness; listlessness and dullness sometimes associated with pronounced apathy; some degree of ataxia, possibly with tremor; numbness, paresthesia, muscular pain perhaps lancinating, pains in the limbs, nerve tenderness, neuritis and paralysis of peripheral or cranial nerves of the chronic type and associated with but little pain and either motor, sensory or mixed. Cerebellar signs, often overshadowed in cases of acute or of subacute involvement, may be the only finding. Ataxia may be accompanied by incoordination and cerebellar gait. Vertigo, one of the frequent and early signs, may be severe and associated with nystagmus, tinnitus and impairment of hearing. Drowsiness by day may be followed by insomnia by night. Retrobulbar neuritis has been reported.²⁹

When other symptoms are present, indigestion is usual and morning anorexia may be associated with some nausea, rarely with vomiting. Generalized abdominal pain is a frequent complaint, and there may be either constipation or diarrhea. Changes on the part of the circulatory system are not considerable. The pulse rate is usually increased.

LABORATORY EXAMINATIONS

Laboratory findings are not remarkable. In acute and subacute intoxication the blood changes are not characteristic; the erythrocyte count is influenced to a great extent by the degree of hemoconcentration and the varying effects of hemorrhage, and the picture, both in the blood and in the marrow, may be further complicated by the effects of benzene present in the gasoline. A reduction in number of erythrocytes and in the hemoglobin content reported as occurring in some cases has been obscured by hemoconcentration in others. The leukocyte count tends in the main to be somewhat elevated and, when pneumonitis is present, may be as high as 20,000 to 30,000, with a relative increase in granulocytes, this increase obtaining shortly after exposure. Later the leukocyte count will be further influenced by the degree of secondary infection in the pneumonitic areas. Moderate eosinophilia of from 3 to 6 per cent has been reported in a number of cases but is not of sufficiently consistent occurrence to have diagnostic value.

The specific effect of gasoline, or benzene, on the blood seems to be elicited only in chronic intoxication. In cases of chronic gasoline poisoning some degree of anemia is usual. Hemoglobin may vary from 60 to 90 per cent, with 3 to 4 million erythrocytes. Leukocytes are little changed, usually slightly increased. In those cases in which leukopenia has been reported there has usually been exposure to gasoline of high benzene content. Thrombopenia, purpura and epistaxis may also occur.

Changes in the blood chemistry are not significant. Urea and total nitrogen may be slightly increased in the presence of acute symptoms. Blood sugar is usually within normal limits. Loewenberg³⁰ noted that in experimental animals the blood cholesterol may be halved, but in man it is only slightly decreased. The assumed direct relationship between concentration of

blood lipids and susceptibility to intoxication has not been confirmed.

Albuminuria occurs in from 10 to 20 per cent of cases and usually appears three or four days after exposure.

SEQUELAE

Mild, nondisabling sequelae probably follow acute intoxication more often than has been reported. Unless severe and persistent, sequelae are difficult of interpretation and simultaneous exposure to other noxious agents, such as carbon monoxide,³¹ often complicates the picture. Serious, clear-cut sequelae have been limited to cases in which exposure was by inhalation, except for one case of Schwarz,¹¹ in which severe polyneuritis lasting seven months followed the daily ingestion of from 3 to 5 cc. of gasoline for a period of from five to six weeks.

The most common of the sequelae are peripheral neuritis, impairment of memory, dulness of intellect, numbness of the extremities, cranial nerve palsies, retrobulbar neuritis and epileptiform seizures. Thus they are limited almost entirely to the central nervous system, although chronic pneumonitis has also been reported in 2 cases.

Epileptic attacks are by far the most serious sequela to acute intoxication. Four instances, 3 of them rather sketchily reported, are on record. In Johnstone's²¹ case acute intoxication from inhalation was followed twenty-four hours later by coma and convulsions, with clonic twitching on the right side. The patient recovered in seven days and worked for two months, at which time he suffered another attack of coma and convulsions in the absence of exposure. During the attacks the pupils were fixed and unequal and there was conjugate deviation and a Babinski reflex was elicited. In the succeeding eighteen months seizures continued, without loss of consciousness in the mild attacks. Examination at this time showed mainly left-sided focal cerebral symptoms, conjugate deviation and the Babinski reflex, with inequality of the tendon reflexes, unilateral muscular twitchings and a fixed facial expression. In Floret's case,³² that of a young girl who suffered an acute attack from the inhalation of vapors, followed by excitement, coma and convulsions, repeated convulsive seizures and periods of excitement recurred frequently for one year after recovery from the acute attack. In the interval, neurologic examinations gave negative results except for slow pupillary reaction. Stiefler³³ reported a case in which coma lasted for three or four days and epileptiform seizures began four or five months after the acute attack. Neurologic examinations gave negative results; the ultimate outcome was not stated. Schneider⁶ made a brief report of a case in which there were retrobulbar neuritis, symptoms associated with degeneration of the cord tract and epileptiform seizures.

Neuritis and paresthesia are not uncommon following acute attacks but do not usually persist; in some cases, however, severe cord or neuritic symptoms have persisted for years. In Dorner's case,³⁴ in which an acute attack caused three days of coma, symptoms of cord disease developed seven months later, and two years

after exposure the patient was still suffering from weakness, numbness of the right hand, intention tremor, unequal pupils, nystagmus, patchy disturbances of sensation, astereognosis, adiadokocinesis and unequal reflexes, a positive Babinski reflex and ataxia. The lesions simulated multiple sclerosis or combined cord diseases, but they were excluded clinically. Potts's³⁵ patient, after four months of variable exposure, had an episode of acute intoxication in which acute symptoms including total external ophthalmoplegia appeared. Coma lasted for hours and the patient was somnolent for eleven days. Four months later he still had paralysis of the third nerve on the left side and weakness of the left arm. A similar case reported by Rutin³⁶ had as its sequel paralysis of the third nerve, persistent vertigo and past pointing. In one of Jansen's³⁷ cases neuritic phenomena developed six weeks after a single severe exposure and progressed steadily. The acute attack was accompanied by coma, mania and confusion lasting for ten hours. The patient's condition was greatly improved in forty-eight hours and he returned to work on the nineteenth day. Six weeks later, weakness, anorexia, headache, insomnia, peripheral nerve tenderness, irregular reflexes and ataxia were noted, and three and one-half years later recovery was not complete. Neurasthenia, areas of paresthesia and transitory neuritic pains persisted. In another case reported by Jansen³⁷ acute intoxication followed inhalation, with tremor, motor unrest and general convulsions. The patient left the hospital in eleven days but on the seventeenth day he complained of headache and tremor and a year later he was found to have facial weakness and deviation of the tongue for which no other cause could be found. Kalinowsky³⁸ reported a case in which an acute attack with multiple hemorrhages and thrombopenia was followed five weeks later by the appearance of painful median neuritis with paralysis of all the muscles supplied. This remained complete for at least one year.

From the cases cited it may be seen that the sequelae of acute gasoline intoxication can involve the higher centers, can be general or focal and can be limited in large part to the cord or to the peripheral nerves. This great variability in kind and in behavior, on the part of the sequelae, is in keeping with the variability in behavior displayed by both acute and chronic intoxication.

DIAGNOSIS

As a rule, acute poisoning offers little difficulty in diagnosis. There is a history of exposure, and the odor of gasoline usually clings to the clothes and skin, sometimes for days. If poisoning has been by ingestion, both vomitus and washings from lavage will have this smell for as long as four days. It will also be detected in the expired air for hours if exposure has been to high concentrations.

There is little that is characteristic about the patient's general appearance. In those who lie quiet, the vasomotor collapse, cold extremities and cyanosis may simulate shock. When muscular twitchings and jactitation

or gross convulsions occur, epilepsy may be simulated. Around petroleum refineries and fields, where the men's clothing usually carries some odor of gasoline, differential diagnosis between acute poisoning by hydrogen sulfide and asphyxia from gasoline intoxication may offer difficulty, but early differentiation is immaterial, since treatment of the asphyxia caused by either agent is the same. Gasoline is frequently handled where internal combustion engines are operating, and consequently gasoline intoxication may be confused with coma and convulsions from carbon monoxide intoxication. The color of the skin and mucous membranes and the finding of carbon monoxide hemoglobin in the blood will serve to identify the latter condition.

Much greater difficulty in differential diagnosis occurs in cases of chronic poisoning and also in the allocation of responsibility for sequelae. Any one of the gastroenteric, cerebral or peripheral neuritic manifestations of chronic gasoline intoxication may occur in infectious, metabolic or degenerative disease, and for this reason great dependence must be placed on the history of exposure to gasoline. Personal inspection of working conditions may be necessary in order to establish the magnitude of the exposure, and the discovery of other cases with similar symptoms in workmen having similar exposure will be of considerable aid.

Sequelae usually do not follow chronic exposure; consequently amelioration of symptoms may be expected to follow cessation of exposure in chronic cases, and this may be the best expedient in establishing the diagnosis. Hysterical or psychoneurotic symptoms in a person with chronic exposure to gasoline should suggest the possibility of intoxication, and relief from these symptoms should follow soon after removal from exposure. In the reported cases in which early multiple sclerosis was simulated, temporal pallor, typical speech and emotional disturbances were absent.

In the interpretation of sequelae it is most useful to remember that severe sequelae have never been recorded except in cases of severe acute intoxication with a history of coma and often of convulsions.

PROGNOSIS

In most cases of acute intoxication there is recovery without serious after-effects; severe sequelae are uncommon. When exposure has been by inhalation the magnitude of exposure or absorption cannot be estimated and prognosis must be based on the patient's condition and clinical behavior. As in other intoxications, prolonged coma or the appearance of convulsions or epileptiform seizures is evidence of severe illness. More definite data are available for exposure by ingestion: In Siwe's⁷ series, 50 per cent of the cases in children were fatal. Nunn and Martin¹⁰ reported a mortality of 28 per cent in children after ingestion of gasoline, as compared with 9.2 per cent mortality following ingestion of kerosene. Patients fatally poisoned lived from two to eighteen hours, and all who died had pneumonia with cyanosis and respiratory difficulty from aspiration. Convulsions occurred in 2 of their fatal cases and in 2 nonfatal, while in one third of their nonfatal cases some aspiration pneumonia was present.

THERAPY

There is no specific treatment for intoxication with gasoline. Removal from exposure and general management are most important. If the material has been

taken by mouth, gastric lavage should be carried out as soon as feasible and should be the first treatment instituted, even though twenty-four or forty-eight hours have elapsed. Gasoline is absorbed only very slowly from the stomach, and washings have had a definite odor of it as long as four days after ingestion. In patients who are comatose, lavage will reduce the frequency of vomiting and will lessen the danger of aspiration of vomitus. If there is no enteritis or diarrhea, saline cathartics and enemas should be given to eliminate any of the material present in the lower part of the bowel.

Embarrassment of respiration is frequent; if breathing stops, artificial respiration should be carried out with oxygen and 6 or 8 per cent carbon dioxide. This treatment was given for eleven hours to a patient aged 2 years, 1 of the series reported by Nunn and Martin.¹⁰ Moreover, since most of the gasoline is excreted by way of the lungs, the course of the acute illness can be definitely shortened if adequate ventilation is secured by administering oxygen and carbon dioxide. Inhalation treatment has the further advantage of lessening the likelihood of pulmonary complications, such as atelectasis and pneumonia, by increasing the respiratory effort and expanding the lungs.

Sudden vomiting or failure of respiration is most likely to occur in the first three or four days of illness, and twenty-four hour nursing attendance is necessary during this time. Dangerous symptoms such as sudden apnea, convulsions or circulatory failure may come on without warning as long as three days after exposure, and the patient should be kept in the hospital under constant observation as long as any active symptoms are present. If evidences of peripheral vasomotor collapse appear, heat should be applied and therapy for the collapse instituted. Response to drugs in the involved vessels is poor and, when possible, physical methods of treatment should be employed. Cardiac stimulants may be necessary; epinephrine should not be used because of its tendency to cause pulmonary edema.

If exposure has been by inhalation, the patient should be removed immediately to fresh air, kept warm and placed in bed as soon as feasible; a cleansing bath should be given to remove any gasoline present on the skin. From this point, the general plan of management is essentially the same as that in poisoning from ingestion, except of course that lavage and cathartics are omitted.

SUMMARY

1. Gasoline is a mixture having a widely variable chemical composition, and poisoning from it produces a variable clinical syndrome. The most prominent symptoms and signs arise from the central nervous system and the gastroenteric tract.

2. The opportunities for exposure to gasoline constitute an increasingly important potential hazard in industry and to the community.

3. Pneumonitis, visceral congestion and hemorrhages are the most frequent pathologic changes.

4. Chronic intoxication from gasoline is rare.

5. Severe sequelae are uncommon and occur only after severe acute intoxication.

6. The history of exposure and estimation of its magnitude are of greatest importance in the diagnosis.

7. Therapy is general and supportive.

Clinical Notes, Suggestions and New Instruments

WESTERN EQUINE ENCEPHALITIS OCCURRING AMONG HUMAN BEINGS IN KANSAS DURING THE SUMMER OF 1941

PRELIMINARY REPORT

JAMES A. WHEELER, M.D., NEWTON, KAN.

During the summer of 1940, Dr. Ketzelman and Dr. Grundaman¹ of Kansas State College made a collection of assassin bugs (*Microtonus purcis*) in a pasture where horses had died of western equine encephalitis. They found that 50 per cent of the collection were infected with virulent western equine virus. In 1941 collections were again made in different pastures with the same results.

The assassin bug is found mainly in pastures along rocks or ledges. It is a semitropical bug which is supposed to have migrated to North America but is now considered fairly common throughout the Middle West. This bug lives on blood from animals or man. It mates and hibernates after frost and lays its offspring along rodent nests so that the young may feed on the rodents until they are old enough to fly. After it can fly, which is in early May, it may then seek out animals in the pasture, especially horses. The bug feeds at night about once a week. It has been found around street lights and also in homes. The spread of horse encephalitis to human beings becomes apparent through this bug as well as other blood sucking vectors. We have been fairly certain that rodents were playing a role as a reservoir for the virus of western equine encephalitis. Last winter we passed the Lansing strain of virus back to the common rat. It is possible in horses that the assassin bug may light up the infection in the spring and then with the influx of mosquitoes the disease would be spread among both horses and man. With these facts and conjectures before us, we set out first to determine the percentage of western equine encephalitis infection among human beings in Kansas.

TESTS

For this investigation it was decided to obtain specimens of blood from reported cases of encephalitis occurring in man over the state. The Kansas State Board of Health consented to cooperate with us and we chose the serum neutralization test and guinea pigs as the test animals. These tests were to determine the negative and positive findings from the specimens of blood taken from the cases sent in by the Kansas State Board of Health. Four guinea pigs were used for each test. In any case in which there occurred an element of doubt, the tests were repeated. These tests were done by Dr. Lee Roderick, head of the Pathology Department, Kansas State College. No effort was made to test for the St. Louis strain of encephalitis virus. These specimens were taken routinely. The specimens came from a number of counties which included a wide area in Kansas. The final results showed that 50 per cent of the patients tested showed evidence of protection or antibodies against western equine virus.

Reference work in the West has shown that the virus of the St. Louis type of encephalitis is present in certain wild and domestic birds and mammals. Since the St. Louis strain has been passed successfully to the horse, it is thought that there may be more of this type of virus found among horses. It has been shown that horses from Colorado as well as from Montana and Washington possessed neutralizing antibodies for equine or St. Louis virus or both. Experimentally, horses were injected intracerebrally and inoculation was made of a proved strain of St. Louis virus. The resulting infection was

indistinguishable clinically from that caused by the western strain of equine encephalomyelitis virus.

Our clinical experience with human beings in this epidemic has shown in clearcut instances that the differential diagnosis on clinical grounds is difficult if not impossible; for example, a white boy aged 8 years in previous good health, whose parents had three weeks before the illness moved to a home near a small stream, had been bitten repeatedly and extensively by mosquitoes. He was sick for three or four days with high temperature. His parents did not call a doctor and it was not until he was up and about that they noticed he was dragging his left foot and he was then brought to the hospital. Examination showed a typical foot drop with anterior paralysis in the left leg, as often occurs in cases of anterior poliomyelitis. The spinal pressure was increased to 26 cm. The cell count was normal. The blood from this boy was tested as a routine measure by the serum neutralization test and to our surprise he gave a strong positive reaction to the western horse virus. Four other patients from our hospital who appeared to have clinical encephalitis had increased spinal pressure, the cell counts ranging from 75 to 100 lymphocytes. These patients were tested by the same method. The latter ones were negative to the equine western horse virus. They were not tested for the St. Louis virus. Of interest is the report of a health officer in Cherokee County, who reported that a man in western Kansas became ill with encephalitis and when he returned some distance to his home one of his horses became ill and died of encephalitis within a period of several weeks. The doctor suggested that the horse could have contracted the disease from this man. The man's blood was tested and found positive for the western equine encephalitis virus.

RESPONSIBILITY OF MOSQUITOES AND WOOD TICKS

Recently Hammon and his co-workers² have reported isolation of the western equine and St. Louis viruses from mosquitoes (*Culex tarsalis*) collected from areas in which cases of human encephalitis occurred. This evidence suggests the vector theory. The *Culex tarsalis* mosquito is common in Kansas. It is reported that nearly all the cases of equine encephalitis among horses occurred among those which were in the pastures and turned out to graze at night. Those which were kept in the barn at night, it was thought, had some protection. The reported clinical cases of both poliomyelitis and encephalitis have occurred in Kansas from week to week in 1940 and 1941 in a pattern that suggests a ratio population incidence. For example, if 5 cases were reported of either disease it would represent five counties—but 1 case to a county. It was a rare instance in a large county when 2 cases to a county were reported in the same week. In Kansas the incidence of poliomyelitis, encephalitis and equine encephalitis ceases abruptly with the fall frosts.

In the October 18 issue of *THE JOURNAL* it was reported³ that in Russia outbreaks of encephalitis occurred a number of years ago. The work among the Russian investigators has shown that wood ticks also played a part in the transmission of the disease. This particular work has probably been overlooked in the past in the light of some of our newer knowledge.

SUMMARY

1. The percentage of western equine encephalitis in reported clinical cases of encephalitis occurring in man in Kansas is being determined.
2. The serum neutralization test was used to determine positive and negative reaction of the patient's blood.
3. In Kansas 50 per cent positive reactions to equine encephalitis were found from the samples of blood taken from cases diagnosed as human encephalitis.

2. Hammon, W. McD.; Reeves, W. C.; Brookman, B.; Izumi, E. M., and Gjulin, C. M.: Isolation of the Viruses of Western Equine and St. Louis Encephalitis from *Culex Tarsalis* Mosquitoes, *Science* 91: 328-330, 1941.

3. New Developments in Knowledge of Encephalitis, editorial, J. A. M. A. 117: 1361 (Oct. 18) 1941.

This work was done in conjunction with Kansas State College, the Kansas State Board of Health and the Committee on Child Welfare of the Kansas Medical Society.

1. Ketzelman and Grundaman: Special bulletin report from Kansas State College, 1940.

4. The vector theory may prove to be a possible cause of the spread of both the western equine and the St. Louis virus.

5. The question of clinical diagnosis and classification of these diseases including poliomyelitis makes it doubtful, if not impossible, to make such a classification. The serum neutralization test should be used as one of the means to help classify virus infections occurring in human beings.

NOTE.—Further work will be undertaken with the St. Louis virus in the future. All negative reactions to western equine virus will be tested on Swiss mice for the St. Louis strain. These tests will be used as a routine measure next year by the state board of health in all cases of reported poliomyelitis and encephalitis. The purpose is to obtain further data on virus infections occurring in Kansas.

PHENOL-CAMPHOR FOR "ATHLETE'S FOOT"

EDWARD FRANCIS, M.D., WASHINGTON, D. C.
Medical Director (Retired), U. S. Public Health Service

I have used a combination of phenol and camphor with success for curing "athlete's foot." This preparation may be compounded as follows:

Melt U. S. P. phenol and measure out 3 cc. into a mortar; weigh 3 Gm. of U. S. P. camphor, break into small pieces and add to the melted phenol. Rub until the entire mass is liquefied. Transfer into a vial with a stopper suitable for use as a dauber. Keep stoppered when not in use. Experiments indicate that the ingredients may be mixed in the proportion of 3 parts phenol and 1 part camphor.

The mixture is nonirritating to the skin and may be painted between the toes several times a day, the small rubber stopper of the vial being used as a dauber. The sock may be replaced immediately without danger of corrosion. There is no discoloration of the clothing. Relief from itching is immediate. It should be pointed out, however, that the phenol-camphor preparation should not be applied to the wet skin, since water causes a breakdown of the preparation, with the result that it becomes caustic.

A trade preparation of phenol, camphor and iodine in proportions which are not stated is the only preparation containing phenol and camphor that I have seen specifically advocated for "athlete's foot." Since, however, there is no statement as to the proportions of the phenol and camphor and since it also has the objection of containing iodine which would stain the skin and clothing, I believe that the simpler phenol-camphor formula is preferable.

It seems remarkable that, with the exception of the trade preparation mentioned, none of the authorities of whom I am aware and who have recommended phenol and camphor for various diseases have pointed out that it may also be useful for curing "athlete's foot."

Thus, for example, the Dispensatory¹ of the United States of America contains the following formula: phenol, 30 parts; camphor, 60 parts; alcohol, 10 parts. This is recommended for the local treatment of erysipelas. Andrews² recommends the same formula for barber's itch. Remington's Practice of Pharmacy³ recommends this formula, but with substitution of liquid petrolatum for alcohol, as an antiseptic in dental practice. Swartz⁴ recommends phenol and camphor, of each 1 ounce (28.35 Gm.), and iodine 1 drachm (4 Gm.) for tinea favosa and tinea capitis, but he does not mention that formula under epidermophytosis, "athlete's foot."

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

UNDER EDITORIAL SUPERVISION OF DRs. LEROY H. SLOAN, MARSHALL DAVISON AND FREDERICK STEIGMANN

THE THERAPY OF MENINGITIS

ARCHIBALD L. HOYNE, M.D.

CHICAGO

PROPHYLAXIS

In the presence of an existing epidemic effective measures that will lessen the likelihood of an attack of meningococcic meningitis are the establishment of free ventilation and the avoidance of overcrowding. Close association with some one already infected is necessary in order to contract the disease, since the survival time of the isolated organism is short. It has been shown¹ that the carrier rate could be reduced in dormitories from 29 per cent to 5 per cent by increasing the space between the beds from 9 inches to 3 feet. Fatigue has been found repeatedly to be a contributing factor in the development of the disease. A well balanced diet is important in any scheme of preventive medicine. An absence or deficiency of all the requirements mentioned are presumed to contribute to the outbreaks of epidemic meningitis which usually develop in time of war or when large numbers of recruits are mobilized.

Known carriers of meningococci seldom contract the disease because of their own immunity. Nevertheless, they are the chief means of conveying the infection to others. For this reason carriers² as well as patients with active disease should be isolated. The minimum quarantine period for a patient suffering from the disease is usually about two weeks. With the advent of intensive chemotherapy with the sulfonamide derivatives, meningococci are not usually isolated from nasopharyngeal cultures following recovery from the acute attack. Carriers who have been treated with these drugs no longer harbor the organism.³

Vaccines have been used with doubtful success for the purpose of active immunization, but Ferry⁴ has reported that a positive intracutaneous reaction caused by meningococcus toxin can be changed to negative in 66.8 per cent or more in those inoculated with three doses of the toxin.

Sometimes antimeningococcus serum or meningococcus antitoxin is administered intramuscularly for the purpose of passive immunization when there has been close contact with a person who has meningococcic meningitis. The real value of such treatment is questionable.

In all other forms of bacterial meningitis, with the exception of influenzal meningitis, some primary focus of infection is usually disclosed by a complete physical

examination. There are no special systemic procedures which can be adopted, with exception of those for tuberculous meningitis (Mantoux, patch test, roentgen ray) which occurs as the result of overcrowded and insanitary living conditions where a tuberculous person has been dwelling.

HISTORY OF THERAPEUSIS

Prior to the twentieth century all forms of bacterial meningitis were nearly 100 per cent fatal. The first real progress in therapy came with the introduction of lumbar puncture by Quinke in 1891 and the development in 1906 of antisera by Kolle and Wassermann⁵ and also by Jochmann⁶ for the treatment of meningococcal meningitis. Soon afterward Flexner (1908)⁷ announced an improved serum which was first used on an extensive scale during the Akron, Ohio, epidemic of meningitis in 1907. For the next twenty-five years antimeningococcus horse serums were used on account of their avowed antibacterial action, and rarely if ever did any one suggest that they possessed antitoxic properties.

INTRASPINAL TREATMENT

These standard antimeningococcus serums were administered intrathecally scarcely without exception until Herrick⁸ in 1918 recommended large doses of antiserum intravenously when meningococcemia was apparent. Nevertheless, the intrathecal method was standard because of the contention that direct contact of the serum with the organisms in the spinal fluid was necessary to destroy the inciting cause of the disease. For this reason, if antimeningococcus serum was not injected intraspinally in the lumbar region it was likely to be given intracisternally or even intraventricularly. The mode of injection was nearly always by gravity after the withdrawal of spinal fluid in excess of the volume of serum that was to replace it.⁹

STANDARD ANTIMENINGOCOCCUS SERUMS

When meningococcal patients were treated with antiserum intrathecally the aim was to eradicate the organisms from the cerebrospinal fluid. To accomplish this purpose opinion differed regarding the frequency with which the serum should be given. Some prominent hospitals adopted a policy of administering antimeningococcus serum intraspinally "every six hours during the first few days," then every twelve hours and finally once in twenty-four hours. At Cook County Contagious Disease Hospital serum was never given more often than once in twenty-four hours. But, regardless of the intervals between intraspinal injections, this form of treatment was continued until laboratory reports specified that one or more cultures of the spinal fluid were negative. In addition, great weight was often attached to a high cell count, and sometimes for that reason alone serum treatment was continued even though no organisms could be demonstrated in the spinal fluid.

FATALITY RATES

There is no doubt that the production of a specific serum for the treatment of meningococcal meningitis exerted a decided influence on the mortality. As compared with preserum days, fatality rates were lowered 35 per cent or more. The statistics at Cook County Hospital show that for the nineteen year period¹⁰ (1915-1933), the average fatality rate was 50.6 per cent (1,815 patients). Fatality rates¹¹ of 60 per cent or more were common. In 1929 the state of Missouri reported 65.3 per cent and in 1930 the Ministry of Health¹² in England announced an appalling figure of 95.1 per cent. During the Detroit epidemic of 1928-1931 inclusive, in which there were 1,686 cases, the fatality rate was 50.5 per cent. At that time the therapeutic results were considered remarkably good.¹³ Chicago had an average fatality rate of 47.8 per cent for 4,028 cases of meningococcal meningitis in a twenty year period (1916-1935).¹⁴ During those years there were some clinicians in Germany who advised against the use of antisera for very young patients, claiming that better results could be secured merely by drainage. Moreover, there existed a general feeling that antimeningococcus serum was often lacking in efficiency.

REASONS OFFERED FOR FAILURE OF INTRASPINAL TREATMENT

Failure with the intrathecal treatment of meningococcal meningitis by antimeningococcus serum was often attributed to lack of agglutinating properties. But, practically, this conclusion was sometimes found to be erroneous because serums with little ability to agglutinate often gave good clinical results, whereas the reverse was not always true.

Besides the early standards of treatment which dictated that antiserum should be given intrathecally to patients with meningococcal meningitis, it has been felt quite generally that drainage of spinal fluid is always essential to avoid the "dangers" of intracranial pressure.

MENINGOCOCCUS ANTITOXIN

Until Ferry¹⁵ reported a soluble toxin (1931) and developed meningococcus antitoxin (1932), little consideration was given to the toxemia of meningococcal meningitis. In November 1933, I made the first clinical trial of Ferry's meningococcus antitoxin at the Cook County Contagious Disease Hospital. In the beginning, the new serum was given intraspinally and also to a lesser extent intravenously,¹⁶ according to a procedure followed sporadically since 1918.¹⁷ As the value of the antitoxin became well established, the amount of intraspinal serum was reduced, while at the same time larger quantities well diluted in 10 per cent dextrose solution were given intravenously. By the end of about one year

intraspinal therapy was discontinued¹⁸ entirely and has not been used since 1935. In looking backward it seems interesting to recall that during a period of approximately thirty years, while continued efforts were being put forth to improve the effectiveness of antiserum, comparatively little attention was directed toward modes of administration other than the intrathecal route.

INTRAVENOUS THERAPY

When serum was administered exclusively by the intravenous¹⁹ route, it was found not merely that fatality rates were sharply reduced but that complications were few and recoveries often took place within a week from the time that treatment was begun. Moreover, opisthotonos and loculations of spinal fluid due to arachnoidal adhesions were not so frequently encountered. In addition, the patient was not subjected to the discomfort, pain and possible injury²⁰ resulting from numerous lumbar punctures and the introduction of an irritating substance into the intrathecal sac.

With the success of exclusive intravenous therapy firmly established, it was soon proved that meningococci disappeared from the cerebrospinal fluid much quicker than when serum was injected intraspinally. Furthermore, it also became apparent that frequent lumbar punctures for the purpose of drainage are not required. The old fear concerning dangers of intracranial pressure was dispelled and the view that no permanent relief from intracranial pressure was derived by frequent lumbar punctures has now gained wider acceptance. In patients suspected of meningococcemia either with or without evidence of meningitis, if a positive blood culture is obtained no lumbar puncture is necessary, although for a general estimate of the severity and for purposes of completeness it is likely that for some time to come lumbar puncture will be performed. It is preferable that no puncture be made. We have treated successfully more than 40 such patients without any lumbar puncture.²¹

THERAPEUTIC POSSIBILITIES

Until the advent of the sulfonamides it was rare that a patient survived any attack of bacterial meningitis other than the meningococcal type. Today the situation is far different. If tuberculous meningitis is excluded, it is justifiable to state that a patient suffering from any form of bacterial meningitis has at least a chance for recovery. And with chemotherapy the technic of treatment has been greatly simplified in the management of meningococcal meningitis. Antiserum is no longer required for the majority of such patients. If, however, the patient is suffering from a severe attack, possibly of a fulminating character²² with a profusion of petechiae or large hemorrhages of the skin, it is best to give at least one large dose (100,000 units) of Ferry's antitoxin or standard antimeningococcus serum (300 cc.) in about 600 cc. of 10 per cent dextrose in physiologic

solution of sodium chloride (0.85 per cent) to which approximately 1 cc. of a 1:1,000 solution of epinephrine hydrochloride has been added. This mixture should be given slowly, starting with 10 to 15 drops a minute and at body temperature, by the drip method. If it seems advisable, this procedure may be repeated. As much as 150,000 units (450 cc.) of Ferry's antitoxin has been given in one dose according to the procedure described, and more than 2,000 cc. has been administered intravenously to a single patient without any serious reaction even though a horse serum was introduced. Tests to reveal sensitivity to horse serum should be performed before the antitoxin is given. If the patient is known to be sensitive to horse serum he should be desensitized before antitoxin is given intravenously. The technic of desensitization by injection of graduated doses of the product is well known. I have expressed the opinion that the diluted antitoxin given intravenously according to my method is no more likely to cause a serious reaction than the undiluted serum or antitoxin given intraspinally.

ROUTINE PROCEDURE

1. The history is taken and a physical examination, urinalysis and blood count are made.
2. Blood is drawn for typing and culture.
3. Nose and throat swabs are taken for culture on Löffler's medium and blood agar plate.
4. A diagnostic puncture is made. If done, a Pandy test, a cell count and a direct smear, should be made, a blood agar plate should be inoculated and fluid should be sent to the laboratory for culture. Chemistry analyses should include one for total protein and for chlorides. A Wassermann test should be made and the pressure of the fluid should be noted.
5. Petechiae should be needled and a smear made of the exudate.
6. Therapy should then be started:
 - (a) Chemotherapy: The majority are given 5 Gm. intravenously of the appropriate sulfonamide and a blood level determination is made the following morning and chemotherapy continued orally.
 - (b) Ten per cent dextrose in physiologic solution of sodium chloride (0.85 per cent) 1,000 cc. is begun.
 - (c) A small blood transfusion, 250 cc., is given if the patient is in poor condition.
 - (d) If the patient requires more fluid, 5 per cent dextrose solution in physiologic solution of sodium chloride or dextrose-saline solution (2.5 per cent dextrose in 0.4 per cent saline) may be used.

These routines are not carried out implicitly as listed here. If the patient appears to have a meningococcal septicemia there is no need for spinal puncture, for the smear from the petechiae or blood culture will demonstrate the organism; chemotherapy is started, dehydration, acidosis and toxemia are being combated with dextrose and fluids; and by the time a reaction from these measures is expected the report of the blood culture will be known. If the response to therapy is poor and blood culture is positive, meningococcus antitoxin is given as outlined. If the blood culture is negative, then lumbar puncture is imperative for a diagnosis and should not be delayed. This procedure is not harmful to the patient, for if the meningitis is not of the meningococcal type the initial therapy is the same and lumbar puncture is merely diagnostic.

It must be remembered that after twelve hours of intensive chemotherapy spinal fluid cultures are often negative.

CULTURES

Nose and throat cultures are taken on Löffler's medium for the purpose of noting the diphtheria organism. Blood agar plates are streaked to disclose hemolytic streptococci. The blood culture is made by placing 10 cc. of blood in 100 cc. of beef infusion broth. The spinal fluid used for culture is first centrifuged and about 1 cc. of the sediment is inoculated into a semi-solid medium consisting of a 0.2 to 0.5 per cent agar in veal infusion broth with ascitic fluid and salt added. The organism recovered from growth then must ferment maltose and dextrose and be a gram-negative diplococcus.

CHEMOTHERAPY²³

In any instance in which there is delay or doubt on the part of the laboratory in confirming or definitely establishing a bacteriologic diagnosis, it is generally advisable to begin treatment with sulfapyridine or sulfathiazole for the following reasons: They are effective in the treatment of meningococcic meningitis; they are the drugs of choice in pneumococcic meningitis; they are also capable of promoting recovery in cases of influenzal meningitis. In case the patient is comatose or possibly irrational, they may be administered intravenously as their respective sodium salts, and a proper blood level (6 to 8 mg. per hundred cubic centimeters) may be quickly established.

Patients with meningococcic meningitis may be treated throughout the course of their illness with sulfapyridine or sulfathiazole. If the patient is treated with sulfapyridine and can take the drug orally from the onset, it is customary to give an initial dose of 4 Gm. or less, depending on the severity of the disease, the weight and the age of the patient. This is then followed by 1 Gm. every four hours. For children a slightly smaller dose of the drug might be adequate, but close adherence to weight in measuring the dosage is not necessary. It is obligatory to keep a close check on the urine and, if there is evidence of blood, sulfapyridine should be stopped and sulfathiazole or sulfanilamide substituted. A similar change in medication should be instituted in case of nausea, vomiting or other evidence of toxicity which can be attributed to sulfapyridine. When these drugs are used it is mandatory that the patient have an adequate fluid intake.

These drugs may also be given rectally, as the sodium salts usually, in a perforated capsule or in a starch solution in the form of a retention enema. They also may be administered through a stomach tube.

If sulfanilamide is used it is usual to give one half the estimated total daily dose initially. This dose frequently ranges from 2 to 4 Gm. and is estimated on the basis of 0.06-0.12 Gm. per pound of body weight, depending on the severity of the disease. If the patient cannot take the drug by mouth, it may be given in 0.8 per cent solution subcutaneously. About 200 cc. of such solution may be given twice a day until oral administration is possible; then 1 Gm. every four hours usually suffices.

The Solutions Laboratory of the Cook County Hospital provides sodium sulfapyridine for intravenous use in 5 per cent solution of physiologic solution of sodium chloride instead of in distilled water, as usually advised. Flasks of 100 cc. will, therefore, contain about 5 Gm. of sodium sulfapyridine and are administered by the drip

method. A blood level for sulfapyridine should be determined on the second day of treatment and should be repeated at least every other day in order to gage the required dosage of the drug properly. As soon as possible, sulfapyridine should be given by mouth instead of by vein. Generally we have aimed to keep the level at 8 mg. per hundred cubic centimeters or higher. This cannot always be done, though we have sometimes attained a level as high as 25 mg. per hundred cubic centimeters for a few days. However, there seem to be definite variations in the manner in which patients respond to sulfapyridine. In some instances in which blood levels were high the patients did not survive, whereas others recovered even though concentrations of the drug in the blood fell to as low as 3 to 4 mg. per hundred cubic centimeters. It is not necessary to make frequent lumbar punctures merely for the purpose of determining spinal fluid levels, which may be no more than 70 or even 50 per cent of the blood levels.

For appropriate purposes, sulfathiazole appears to be effective with lower blood levels than those usually required with the other sulfonamides. Blood levels of from 4 to 5 mg. per hundred cubic centimeters have seemed to be adequate. Rashes, conjunctivitis and erythema nodosum may develop during the course of treatment but are not common. Gastric distress or mental confusion does not occur.

If intravenous administration is necessary or seems advisable, sodium sulfathiazole can be injected. The manner and size of the dosage is similar to that of the related drugs. A 5 per cent solution of sodium sulfathiazole in physiologic solution of sodium chloride is also supplied by the laboratory although it has been claimed that no other solvent but distilled water should ever be used. Sulfathiazole should never be given in dextrose nor in blood for transfusions. It should always be administered from a clean vessel and through sterile tubing not recently used for any other purpose. It has been stated that sulfathiazole does not pass readily into the cerebrospinal fluid. On the basis of our limited experience we doubt the correctness of that opinion.

After the acute symptoms have come under control the "sulfa" drugs are continued at a reduced dosage. The patient is usually off all medication in eight days but to continue medication at reduced dosage lessens the possibility of relapse or of complications.

*Sulfadiazine.*²⁴—This member of the sulfonamide group has been used for a great deal of clinical experimentation during the past year. It is claimed that sulfadiazine is less toxic than sulfapyridine or sulfathiazole and yet is as effective as either one of these drugs. Thus far sulfadiazine has not been obtainable for the treatment of meningitis in the Contagious Disease Department of Cook County Hospital. However, a report²⁵ of fourteen patients successfully treated with this drug has recently appeared. The use of this drug at present is in the experimental stage and should not be used as a routine until its place has been established.

MENINGITIS

Streptococcic Meningitis.—This responds well to sulfanilamide treatment. The procedures are the same as those described for meningococcic meningitis. Con-

24. Finland, Maxwell, Strauss, Elias, and Peterson, O. L.: Sulfadiazine: Therapeutic Evaluation and Toxic Effects on Four Hundred and Forty-Six Patients, J. A. M. A. 116: 2641-2647 (June 14) 1941.
25. Dingle, J. H.; Thomas, Lewis, and Morton, A. R.: The Treatment of Meningococcic Meningitis and Meningococcemia with Sulfadiazine, J. A. M. A. 116: 2666 (June 14) 1941.

23. With the rapid advance in chemotherapy, it is understood that the physician will appreciate the use of the "appropriate" sulfonamide and not allow his therapeutic technic to be harnessed to a single derivative.

trary to our experiences of years ago, we now anticipate that the patient with streptococcic meningitis will recover with proper treatment. Convalescent serum has been used as an adjunct to chemotherapy.

Pneumococcic Meningitis.—This was formerly almost as fatal as tuberculous meningitis. Within the past three years we have witnessed no less than 14 recoveries.²⁶ In one half this number specific type serum and also sulfanilamide or sulfapyridine were given. If serum is to be used, and generally such a decision is advisable, a culture from the spinal fluid is necessary and typing of the organism is required. The specific type rabbit serum in doses of from 200,000 to 400,000 units is administered intravenously. A total dose of more than 700,000 units has been given to a patient, and the same procedure is adopted as when a horse serum is being administered intravenously. Lately several patients with pneumococcic meningitis have been treated successfully without the use of specific serum. Among the latter group was a 6 year old girl with type III infection. During her first hospital day she received 8 Gm. of sodium sulfapyridine intravenously and after that 1 Gm. of sulfathiazole by mouth every four hours. She had one lumbar puncture for the purpose of diagnosis. Recovery was complete in one week.

It seems quite likely that eventually it will be found that chemotherapy without serum is as effective in the treatment of pneumococcic meningitis as similar therapy is for meningococcic meningitis. The dosage of the sulfonamides for pneumococcic meningitis may follow the customary guides for the drug used. Nevertheless, it has seemed advisable to lean toward massive doses of the drug at the beginning of treatment and to reduce the size of the dose only in accordance with the progress made by the patient. I have had blood levels as high as 25 mg. per hundred cubic centimeters for patients who recovered when sulfapyridine was used. Moreover, in these instances there was comparatively little gastric disturbance and no abnormal urinary conditions.

Influenzal Meningitis.—This responds also to chemotherapy, and on the basis of my own experience there appears to be an element of doubt as to whether better results are obtained by the combined use of antiserum and one of the sulfonamides than by administration of the drug alone. However, the antisera now available seem to be of value. Fothergill's anti-influenzal serum may be obtained from the Massachusetts State Board of Health. Alexander's Anti-Haemophilus Influenza Type B Serum (rabbit) is supplied commercially in 25 mg. vials. At least 50 to 100 mg. should be administered to a patient if this form of treatment is adopted in conjunction with chemotherapy. Although instructions accompanying the package recommend both intraspinal and intravenous injections, we have adhered to the exclusive intravenous route, employing the same technics as for other serums used in the treatment of meningitis. Alexander also advises daily lumbar punctures, a practice that we condemn. Usually our routine consists in large doses of sodium sulfapyridine intravenously after a lumbar puncture has permitted a laboratory diagnosis by examination of the spinal fluid. For the first two or three days it may seem advisable to give from 8 to 10 Gm. each twenty-four

hours in 4 to 5 Gm. doses about twelve hours apart. Occasionally the temperature of a patient with influenzal meningitis will remain almost stationary on a high plane of approximately 104 F. even though large doses of sulfapyridine are being given to the patient. Under such circumstances it is well to substitute sulfathiazole. This change of drug is sometimes very effective. In fact there are some who believe that sulfathiazole is always the drug of choice for the treatment of influenzal meningitis. Others have reported favorable results with sulfanilamide.

Often blood transfusion will prove to be a valuable adjunct in the treatment of any form of meningitis; for influenzal meningitis this is particularly true. It is always well, therefore, to take the necessary steps to secure appropriate blood donors as soon as a diagnosis of influenzal meningitis has been established. We believe that drainage of the cerebrospinal fluid is no more a necessary part of the treatment of influenzal meningitis than for any other form of meningitis. Moreover, since we have seen more than 16 patients with influenzal meningitis recover who were treated in accordance with these principles of therapy, our optimistic attitude seems justified.

Staphylococcic Meningitis.—This is less frequently encountered than any other of the meningitides previously mentioned. Fatality rates are likely to be higher. Recently it was stated that the total number of reported recoveries was but 9. In the Cook County Contagious Hospital there have been 2 recoveries. One patient was treated with sulfanilamide and the other with sulfathiazole. Both received blood transfusions. One lumbar puncture was made on the sulfathiazole-treated patient. The blood level varied from 3 to 4 mg. per hundred cubic centimeters during most of the treatment. Although these levels seem low compared to the requirements for other sulfonamides, apparently they are adequate.

Generally, it is advisable to give as an initial dose from 3 to 4 Gm. intravenously and follow this by 1 Gm. of sodium sulfathiazole every four hours. It is usually felt that as few doses as possible should be given intravenously because of the danger of thrombosing vessels. It is also possible to cause sloughs if the solution of sulfathiazole enters the tissues.

NURSING CARE

Patients suffering from bacterial meningitis should be isolated. Proper disinfection and disposal should be made of the secretions from the nose and throat, the urine, blood and spinal fluid.

For their protection and that of others, the physician and the nurse should not contact a patient with meningitis unless they are in complete good health, are not unduly fatigued and have no infection of the upper respiratory tract. Any grossly contaminated article should not be touched with the bare hands. In their care of the patient all attendants should wear gowns. Careful attention should be paid to washing the hands and avoiding the spray from the nose and throat of the patient. Masks are proper equipment for attendants and nurses inexperienced in the care of contagious diseases.

The room should be kept quiet and preferably at a constant temperature, and the eyes of the patient should be protected from strong light. When a bath is given,

26. Rhoads, P. S.; Hoyne, A. L.; Levin, Benjamin; Horswell, R. G.; Reals, W. H., and Fox, W. W.: Treatment of Pneumococcic Meningitis, J. A. M. A. 115: 917-922 (Sept. 14) 1940.

the water should be warm, and only a small area of the patient's body should be exposed at one time. The nurse must be unusually gentle in her handling of the patient.

Well padded side boards of beds or of cribs are used if necessary to protect the patient from injuring himself. If a nurse cannot be in constant attendance and side boards are insufficient, the opposite wrist and ankle are restrained by padded shackles.

Tepid sponges for reduction of temperature are given only as ordered by the physician and are rarely indicated.

It is the duty of the nurse to see that the patient maintains a normal intake of food and fluid but not to force either to the point of nausea. This is accomplished by giving frequent small feedings of any food desired and extra fluids between meals.

The nurse should observe and record accurately (a) symptoms of opisthotonos, rigidity of the neck, petechiae, nausea and vomiting, earache, headache, nasal discharge, disorders of the eyes or any unusual change, and (b) drugs given, noting the dosage and time taken, any emesis of medication with repetition of the dose or any untoward symptoms such as nausea or mental disturbance which may result. She should watch the intravenous administration to prevent the fluids from entering the subcutaneous tissues. If antitoxin is given, the solution should be warmed before and during administration. The nurse should watch carefully for signs of anaphylactic shock or serum sickness. It is, of course, her duty to assist the physician in the various procedures of drawing blood, making a lumbar puncture or giving intravenous therapy.

GENERAL RECOMMENDATIONS FOR THE TREATMENT OF BACTERIAL MENINGITIS WITH COMMENTS

1. A lumbar puncture should be made for diagnosis. This may not be necessary in early cases of meningococcemia.

2. No intraspinal therapy of any description should be given. As much harm as good may result from intrathecal treatment.

3. Frequent lumbar punctures for the purpose of drainage should be avoided. The old theory that intracranial pressure is permanently relieved by multiple withdrawals of cerebrospinal fluid is fallacious. The opposite effect is often produced.

4. When chemotherapy is resorted to maximum doses of the appropriate drug should be given at the beginning of the treatment, not at the end, at which time it is less effective.

5. If an animal serum is given intravenously, it should be well diluted in saline solution, not distilled water. If dextrose is chosen, the vehicle should still be saline solution, and epinephrine hydrochloride should always be added before the intravenous flow is started.

6. Opiates should not be administered to meningitis patients. Morphine may cause or increase existing edema of the brain. Comparatively few meningitis patients require sedatives.

The treatment of meningitis today need not be encumbered with the many difficulties which formerly attended it. Successful therapy depends now more on good judgment than on expert skill.

25 East Washington Street.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
HOWARD A. CARTER, Secretary.

TELEX HEARING AID, MODEL 900, ACCEPTABLE

Manufacturer: Telex Products Company, 1645 Hennepin Avenue, Minneapolis.

The Telex Hearing Aid, Model 900, is said by the manufacturer to be designed for slight cases of deafness. Its use is advocated for individuals whose hearing loss is under 50 decibels. In the Council examination the device was found to consist of one microphone and amplifier unit, disk shaped, $2\frac{1}{2}$ inches in diameter by $\frac{3}{4}$ inch, weight 2.6 ounces; one crystal receiver, 1 inch diameter by $\frac{3}{8}$ inch, weight 0.2 ounce (without earpiece); one 30 volt W-20 B battery; one 1.5 volt 2-ES A battery; A and B battery assembly in leather case, $4\frac{1}{2}$ by $2\frac{1}{2}$ by $1\frac{1}{4}$ inches, weighing 11.8 ounces.

Following are results of the Council's investigation:

BATTERY DRAIN

The A battery current shown was 65 milliamperes independent of volume setting and sound. The B battery current was independent of volume setting. With no sound, it showed a current of 0.9 milliamperes and with sound a current varying from 0.5 to 0.8 milliamperes, depending on the sound intensity.

INTERNAL NOISE

The internal noise was not excessive. With a well fitted earpiece, there was no feed-back when the volume control was set for full volume.

ACOUSTICAL GAIN

The figures given in the accompanying table are typical of the acoustical gains as shown by audiometric measurements

Acoustical Gains

	128 256	512-2,049		4,096
		Min.	Max.	
At normal ear threshold set for full volume	nil	21	36	10 decibels

ARTICULATION

The usual articulation tests using hard of hearing subjects were made and showed satisfactory performance.

The Council voted to accept the Telex Hearing Aid, Model 900, for inclusion on its list of accepted devices.

ACOUSTICON, MODEL A-45, ACCEPTABLE

Manufacturer: Dictograph Sales Corporation, 580 Fifth Avenue, New York.

The Acousticon, Model A-45, was examined by the Council and was found to consist of the following items:

Microphone and Amplifier Unit, Model A-45, number 007647
A battery Acousticon No 26, 1.5 volts
B battery Acousticon No 41, 30 volts
B battery Acousticon No 39, 24 volts
B battery Acousticon No 37, 18 volts
B battery Acousticon No 35, 12 volts
1 crystal receiver
1 magnetic receiver
1 bone conduction receiver
1 leather battery case

Weights and dimensions of various parts are as follows:

	Dimensions	Weight	Current Drain, Milliamperes
Microphone and Amplifier Unit Ovoid Shape	$2\frac{1}{2}$ " x 4" x 1"	4.7 Oz.	60-70
A-battery, No 26	$1\frac{1}{4}$ " Diam x $2\frac{3}{4}$ "	3.5 Oz.	1.1-2.2
B battery, No 41	$2\frac{3}{8}$ " x 3" x 1"	5.8 Oz.	1.0-1.6
B battery, No 39	$2\frac{3}{8}$ " x $2\frac{1}{2}$ " x 1"	4.8 Oz.	0.5-0.9
B battery, No 37	$2\frac{3}{8}$ " x $1\frac{1}{2}$ " x 1"	3.5 Oz.	0.25-0.4
B battery, No 35	$2\frac{3}{8}$ " x $1\frac{1}{4}$ " x 1"	2.4 Oz.	
Crystal receiver (without earpiece) 1 inch in diameter by $\frac{3}{16}$ inch			
Magnetic receiver (without ear mold) $\frac{3}{8}$ inch in diameter by $\frac{1}{2}$ inch			
Weight 0.35 ounce			
Bone conduction receiver, weight 0.64 ounce			

The A and B batteries are assembled by means of a spring clip connector and carried in the leather case.

The manufacturer recommends B-batteries as follows:

With bone conduction receiver.....24 and 30 volts
With magnetic receiver.....18 and 24 volts
With crystal receiver.....12 and 18 volts

With these combinations and a carefully fitted ear mold, the instrument could be turned up to full volume without feedback squeals. However, the 18 volt battery with the crystal receiver requires very careful fitting of the ear mold to meet this test. Noise due to rubbing or impact on the microphone case was rather high with the crystal receiver.

Acousticon, Model A-45

ACOUSTICAL GAIN

The following figures give the order of magnitude of the increase in sound intensity levels at the ear of the subject over those at the microphone under conditions of actual use as shown by audiometric measurements. They are not the same as the electrical amplification shown by measurements of electrical input and output.

Receiver	B Voltage	Volume	128	256-2,048	4,096 Cycles
Crystal	18	Full on	Nil	20 to 48	10 decibels
Magnetic	18	Full on	Nil	6 to 32	12 decibels

ARTICULATION

Syllable and sentence lists were used with hard of hearing subjects at a distance of 5 feet in a quiet room, using various combinations, with volume set for comfortable loudness. Satisfactory results were shown with crystal and magnetic receivers and with the bone conduction receiver.

The Council voted to accept the Acousticon, Model A-45, for inclusion on its list of accepted devices.

ALADDIN HEARING AID, MODEL NO. 7, ACCEPTABLE

Manufacturer: National Electronics, Inc., Schenectady, N. Y.

Distributor: Electronic Sales Company, 74 Chapel Street, Albany, N. Y.

The Aladdin Hearing Aid is a wearable vacuum tube instrument. The firm states that the unique feature of the device is the manner in which the amplifier and all the batteries are combined in a single assembly called the "Unipak."

In the Council examination the device was found to consist of the following items:

- One battery and amplifier unit.
- One microphone.
- One crystal receiver, 1 inch in diameter.
- One midget crystal receiver, 3/4 inch in diameter.

The A and B batteries and the amplifier are incorporated in a single unit in a leather covered metal case. This unit measures

Aladdin Hearing Aid Model No. 7

5 1/2 inches by 3 inches by 1 1/4 inches and weighs 436 Gm. (15.4 ounces). Volume control is effected by a single knob on the top of the unit. The microphone is a flat disk 1 3/4 inches in diameter, 3/8 inch thick, weighing 26 Gm. (0.92 ounce). Connectors are of the prong in hold type and well made.

The A battery is a 1 1/2 volt battery 1-ES. The B battery is an Aladdin No. EP-424, 27 1/2 volts.

Following are results of the Council's investigation:

Current Drain.—The A battery drain with control set for full volume was found to be 65-70 milliamperes. The B battery showed a current of 1.2 milliamperes.

Internal Noise.—The internal noise level was not excessive and the instrument was comparatively free from noise due to shock. There was very slight tendency to "feed back" squeals.

Acoustical Gain.—The following are typical of the increase in sound intensity levels at the ear of the subject with molded earpiece over that at the microphone as shown by audiometric measurements.

With Intensity at Microphone Approximately 40 Decibels Above Normal Ear Threshold

Measurements with a hard of hearing subject were uncertain because of inductive pickup of the audiometer signal, but they indicated that the gain was not materially less than those shown above.

With Normal Ear Threshold Intensity at Microphone

Vol. Setting	Receiver	128-256	Gain	
			512-2,048	4,096
Full on	1 inch receiver	None	11-30	10 decibels
	Fitted earpiece.....			
Full on	3/4 inch receiver....	None	11-29	4 decibels

Articulation.—Syllable and sentence tests with hard of hearing subjects showed satisfactory performance.

The Council voted to accept the Aladdin Hearing Aid for inclusion on its list of accepted devices.

WESTINGHOUSE MAZDA RS SUNLAMP ACCEPTABLE

Manufacturer: Westinghouse Electric & Manufacturing Company, Lamp Division, Bloomfield, N. J.

The Westinghouse Mazda RS Sunlamp is described by the firm as a self-ballasting mercury vapor lamp equipped with its own built-in reflector. The reflecting surface, being deposited on the inside of the R-40 bulb, is protected from corrosion and dust; this fact, according to the firm, provides for a high maintenance of the output throughout the life of the lamp. The internal ballast consists of a tungsten filament resistance which operates at incandescence and radiates infra-red to provide comfortable warmth in the beam.

Following are data submitted by the firm:

Essential Technical Data

Watts	275 (combined mercury vapor arc and ballast)
Volts	110-125 (50-60 cycle A. C.)
Outer bulb designation.....	R-40
Material	Ultraviolet transmitting glass
Finish	Light inside frost-reflecting neck
Inner bulb	Quartz
Base	Medium screw
Maximum overall length.....	6 5/8 inches
Burning position	Any
Life	400 application
Erythema time	Approximately 5 minutes at 24 inches
Beam characteristics	40° divergence to 30% of axial intensity

The spectral energy distribution in the ultraviolet region produced by this lamp is as follows:

Manufacturer's Results		Council's Results	
Wavelength, Angstroms	Microwatts per CM ² at 30 Inches	Microwatts per CM ² at 24 Inches	
3,129	215.0	Lamp No. 23	210
3,022	76.0		214
2,967	28.0		98
2,925	3.2		50
2,894	4.7		
2,804	1.4		
2,753	0.1	Too low to measure	
Total 228.4 uW/cm ²		273	362 uW/cm ²

This total radiation output equals two to three times minimum requirements of the Council on Physical Therapy.

Fluoroscopic examination of the lamp by the Council confirmed the manufacturer's observations showing that the ultraviolet radiation of wavelengths shorter than 2,800 A is absent. Spectral measurements showed that in spectral quality and total intensity these lamps comply with the Council's requirements for acceptance as a "sunlamp."

The Council voted to accept the Westinghouse Mazda RS Sunlamp for inclusion on its list of accepted devices.

PHYSIOLOGIC ANATOMY OF POLIOMYELITIS

When a ventral horn cell of the spinal cord is destroyed by the virus of poliomyelitis, all muscle fibers normally innervated by the affected neuron degenerate and ultimately disappear. It is not widely appreciated that muscles responsible for locomotor movements are made up of clusters of skeletal muscle fibers which receive innervation from single anterior horn cells. The ultimate physiologic unit of the reflex, therefore, is not the single muscle fiber but rather the group of muscle fibers controlled by one ventral horn cell; to designate such groups, Eccles and Sherrington¹ have introduced the convenient term "motor unit." They have found, after causing all sensory fibers from a given muscle to degenerate, that the motor nerve fibers to a skeletal muscle can be counted, and it was incidentally disclosed that the nerve supplying such a muscle actually contained more fibers near the muscle than at more proximal points. From this they concluded that individual axons must divide as they approach the muscle. Through teasing the nerve trunk as it ramifies in the muscle mass they confirmed this deduction, and they were able to demonstrate the existence of widespread bifurcation of the individual axons within the muscle substance.

Dean Clark,² in a paper which is now a classic in neuromuscular physiology, disclosed that individual nerve fibers passing to soleus and gastrocnemius muscles of cats supply an average of one to two hundred skeletal muscle fibers. After causing degeneration of all sensory fibers, Clark enumerated the remaining motor nerve fibers, and he also counted the number of muscle fibers in the muscle in question. For the soleus he obtained an innervation ratio of 1 to 120 and for the extensor longis digitorum 1 to 165. Similar innervation ratios are known to exist in man from the early

studies of Tergast,³ who, however, failed to make allowance in his calculations for sensory nerve fibers. It follows from this that, when one anterior horn cell succumbs to the virus, not less than one hundred muscle fibers undergo atrophy and die. From embryologic study one knows that the emergent nerve fibers from the spinal cord attach themselves to a closely knit group of muscle fibers. The Swedish pathologist Gunnar Wohlfart has observed in poliomyelitis⁴ and amyotrophic lateral sclerosis⁵ that degeneration of muscle fibers follows a pattern, not of muscle fibers, but rather of discrete muscle fasciculi. In examining sections of atrophic poliomyelitis muscles one frequently finds complete atrophy of all striated muscle fibers in a given fasciculus, while in the next fasciculus the majority of fibers appear healthy and intact. It is possible, therefore, that the muscle fasciculus may in many instances represent the motor unit. Sometimes, however, only half or a third of a fasciculus is affected, but in these instances the degenerating fibers are closely grouped and are not scattered indiscriminately through the fasciculus.

Denny-Brown, who has recently come to this country as professor of neurology at Harvard, points out in a recent paper with Pennybacker⁶ that in certain irritative neuromuscular diseases individual muscle fiber are affected in such a way as to give rise to fine twitching along the muscular surface. This is true "fibrillation" and results from abnormal irritability of individual muscle fibers; "fasciculation," on the other hand, involves large groups of fibers which tend to respond simultaneously and involuntarily. Fibrillation arises from disordered metabolism of the individual muscle fiber, fasciculation from irritative disorders of the ventral horn cell or its axons (e. g. in amyotrophic lateral sclerosis⁵).

In considering the physiologic anatomy of poliomyelitis and the therapeutic measures designed to benefit patients with poliomyelitis, it is thus highly important to visualize the motor unit; for it is the unit as a whole, rather than the individual fiber, that degenerates. Some units are larger and some small, and it is probable that the larger ventral horn cells control the larger units (Sherrington). Similarly some muscle fasciculi are large and some small, but one cannot yet generalize concerning the precise relation of the motor unit to the muscle fasciculi.

2. Clark, D. A.: Muscle Counts of Motor Units: A Study in Innervation Ratios, Am. J. Physiol. 96: 296 (Feb.) 1931.

These physiologic and anatomic considerations have a direct bearing on the therapeutic measures and practices recommended for the treatment of poliomyelitis. At one time it was believed that in early cases of poliomyelitis complete immobilization should be done as far as the affected muscles were concerned. Several years ago Sister Kenny in Australia recommended that free movement should be allowed and that affected muscles should be accorded the benefit of massage and passive movement instead of immobilization. It should be pointed out in this connection that there is no experimental evidence to support the contention that single muscle units might, as a result of appropriate manipulation, be encouraged to send their nerve fibers to muscle fibers which had been rendered atrophic by anterior horn cell degeneration. Normal units, however, become atrophic under conditions of immobilization, since muscle fibers are dependent for normal stimulation on their local reflexes (e.g., stretch reflexes) and immobilization arrests the flow of these proprioceptive impulses as effectively as it abolishes the flow of lymph. Massage and freedom of movement, therefore, are clearly indicated if all available motor units in paretic muscles are to retain their maximum physiologic capacity.

THE FOURTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Because industrial health is a necessity in defense production, the problems of maintenance of health in industry continue to grow in importance and extent. Many physicians are beginning to express interest in industrial appointments not only as a direct contribution to preparedness but because they sense values in industrial health which provide opportunity for interesting and beneficial professional careers. The program of the fourth annual Congress on Industrial Health, which is published in the Organization Section of this issue of *THE JOURNAL*, is designed to intensify this interest and to attract the attention of the profession as a whole to those aspects of industrial practice for which medical leadership and initiative are required. Industrial physicians cannot shoulder the responsibility alone; it is equally the concern of physicians in private general practice and in the specialties.

The training of physicians for satisfactory medical service in industry still is encountering obstacles through lack of information about what needs to be taught and available sources for obtaining teaching personnel and clinical facilities. Discussions of undergraduate and postgraduate industrial medical teaching will therefore occupy a prominent place in the program. Present

plans for training and placement need integration with the program of the newly organized machinery for assignment of medical personnel in industry, details of which will be presented by a representative of the Procurement and Assignment Service. Conservation of manpower is a primary industrial objective in war time, and plans which have been developed jointly by industry and a state medical association will be presented. Since it is illogical to train candidates for exacting skills who are unfitted physically or temperamentally for such work, job placement in industry is of exceptional current interest. The practical aspects of this important phase of medical service will be presented from the governmental, industrial and teaching points of view.

Special reports will be available for presentation during this congress. A joint statement prepared by the Council on Foods and Nutrition and the Council on Industrial Health evaluating vitamin rationing in industry will be presented. Dermatoses continue to occupy first place in claims for occupational disease compensation. A committee representing the Section on Dermatology and Syphilology will submit a report in which definitions of industrial dermatoses and primary skin irritants will be discussed, as well as the criteria for diagnosis of cutaneous afflictions of occupational origin. In a similar manner the Committee on Industrial Ophthalmology of the Section on Ophthalmology is preparing a preliminary statement about the bases for dependable appraisal of vision in industry and the related problems of correction. Lectures on important topics under the general heading of industrial medicine and traumatic surgery will be introduced as a powerful impetus toward improved standards of medical service in industry. These lectures will be a regular feature of all subsequent congresses.

Other important subjects for discussion include the question of medical service to small industry, with particular reference to free choice of physician for specific services, and the evaluation of technics and equipment for mass chest surveys, which are being applied more and more to supplement industrial physical examination programs. Special events include field trips to industrial medical departments for physicians interested in details of practical administration. A clinical program has been arranged in conjunction with the faculty of the University of Illinois College of Medicine.

This program illustrates once again that it is difficult to discover a field in either the basic or clinical medical sciences which has not contributed to or been affected by health problems in industry. The Council anticipates that each succeeding congress will reemphasize this important relationship.

Current Comment

ADDITIONAL APPROPRIATIONS ASKED FOR CONSTRUCTION OF HOSPITALS

On November 28 Representative Lanham of Texas, author of the original measure passed by Congress in June 1941 authorizing the expenditure of \$150,000,000 for community facilities in defense area communities, introduced a bill to increase this amount by another \$150,000,000. Washington reporters say that the bill will receive speedy passage by Congress. On December 1 there were on file with the Federal Works Agency in Washington over three thousand applications for federal funds, totaling nearly \$800,000,000, for the construction of schools, sewerage systems, hospitals and other community facilities authorized under the Lanham act. Over five hundred of these applications were for hospitals, health clinics and health centers, calling for the expenditure of \$140,000,000 in federal funds, which if approved would have left only \$10,000,000 for the numerous other community facilities provided for under the act. The Federal Works Agency has already approved one hundred and twenty-six of the hospital, health center and health clinic projects, which involve about \$21,000,000 in federal funds. Presidential approval, also necessary under the act before funds can be expended, has not been received for all of these. As of December 1, eighty of the one hundred and twenty-six applications had received presidential approval, with about \$12,000,000 in federal funds allocated to them. Officials of the Federal Works Agency state the \$150,000,000 appropriated under the original act is about exhausted, and possibly funds from the new bill will be necessary to take care of some of the forty-six projects already approved by FWA and now awaiting presidential signature.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

Elsewhere in this issue appears a new department of THE JOURNAL entitled "Procurement and Assignment Service for Physicians, Dentists and Veterinarians." Since this is the first time this department has appeared, the record covering the inception and establishment of this bureau is provided in detail, together with a complete list of the various committees which are to function in an advisory capacity to the board that directs the service. Major Sam F. Seeley has been detached from the United States Army Medical Department to serve as executive director in a full time capacity. A regional office has already been established in the headquarters of the American Medical Association to utilize the roster of physicians prepared by the American Medical Association. Similar rosters are in process of development in the headquarters of the American Dental Association and the American Veterinary Medical Association, which also are located in Chicago. The Committee on Medical Preparedness of the American Medical Association has been called

for a special session to take place in the near future, at which time means will be developed for cooperation of this committee in the various corps areas and of the state and county committees on medical preparedness with the Procurement and Assignment Service. Liaison officers have been appointed representing each one of the government services which utilize physicians and which will in the future procure its personnel through the Procurement and Assignment Service as far as possible. The technic proposed is experimental. There seems to be every indication, however, that it can function successfully. The complete cooperation of the medical profession of the country with this service will, of course, do much to aid its efficiency. In times like these, with the tremendous demands now being made on the medical profession, the desirability of attempting to assign every physician to the special function for which he is best suited and the necessity of utilizing every capacity of every physician to the utmost in the continuance of his civilian practice, in medical teaching, in industrial medicine, in the Army, Navy and Public Health Service or in any number of the many ways in which physicians now serve, cannot be questioned.

OVINE VENEREAL ULTRAVIRUS

A venereal infection of sheep due to an ultravirus has been described by Tunncliffe and Matischeck¹ of the Veterinary Research Laboratory, Montana State College. Venereal infections of sheep have been prevalent in certain areas of the United States for more than thirty years. One disease is popularly known as "pizzle rot," "foul sheath" or "venereal form of lip and leg ulceration." The infection is characterized by ulceration and scab formation, the lesions being most common at the preputial orifice or on the lips of the vulva. In the male the penis may be involved, severe balanitis usually resulting in phimosis or paraphimosis. The balanoposthitis is usually regarded by veterinarians as one of the many gangrenous conditions of domestic animals produced by *Actinomyces necrophorus*. In eleven infected ewes and rams recently examined in the Montana State Laboratory, *necrophorus* bacteria were not found. In aerobic and anaerobic cultures bacteria were not noted constantly present in all lesions, with the exception of a small gram-negative bacillus, which proved to be noninfective if swabbed into the scarified venereal surfaces of normal sheep. Experimental transmission, however, was readily accomplished by similar application of bacteria-free filtrates of diseased tissues. Typical lesions were produced by these filtrates, and the disease again transmitted by filtrates from the filtrate-produced cases. The size, antigenicity and chemotherapy of the ultravirus presumably present in these filtrates and its pathogenicity for other animal species have not yet been reported by the Montana investigators. Evidently, however, they have discovered promising material for basic virus research, with numerous suggestive clinical applications.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

The Procurement and Assignment Service was approved by the President on October 30. The creation of this service resulted from a recommendation of the Subcommittee on Medical Education of the Health and Medical Committee to the Health and Medical Committee on March 31. Following a meeting of the Health and Medical Committee on April 28, this recommendation was transmitted by the Health and Medical Committee to the Committee on Medical Preparedness of the American Medical Association for its consideration. The Committee on Medical Preparedness presented this recommendation to the House of Delegates of the American Medical Association at its meeting in Cleveland, June 2 to 5. At this meeting the House of Delegates adopted the following resolution:

WHEREAS, The President of the United States has declared that we are in a state of unlimited emergency, and the Surgeon General of the United States Army requested the American Medical Association in June 1940 at the annual session to aid in the procurement of the necessary personnel for an army of 1,500,000 men; and

WHEREAS, The American Medical Association established a Committee on Medical Preparedness which has now on hand the records of approximately 150,000 physicians as well as a statement as to their training, experience and specialization; and

WHEREAS, The sudden entrance of the United States into a war might immediately require the services not only of the physicians already called to duty but of a very considerable additional number, and

WHEREAS, Neither the American Medical Association nor any other civilian agency has the responsibility or the authority for the selection of those physicians who would be necessary for immediate duty and who would be called for civilian practice into service with the military agencies; therefore be it

Resolved, That the United States government be urged to plan and arrange immediately for the establishment of a central authority with representatives of the civilian medical profession to be known as the Procurement and Assignment Agency for physicians for the Army, Navy and Public Health Service and for the civilian and industrial needs of the nation

This recommendation is made to avoid or minimize confusion and the inevitable delay which would result from the lack of such an arrangement. It is further recommended by the Committee on Medical Preparedness that, if this resolution is approved by the House of Delegates, a copy of it be sent to the President of the United States, the Secretary of War, the Secretary of the Navy, the Chairman of the Senate and House Committees on Military Affairs, the Administrator of the Federal Security Agency, the Surgeon General of the United States Army, the Surgeon General of the United States Navy, the Surgeon General of the United States Public Health Service, the Adjutant General of the Army, and the Health and Medical Committee.

The Health and Medical Committee voted to adopt these recommendations in principle and forward them to the Coordinator, with the suggestion that he consult with the Secretary of War and the Secretary of the Navy and that matters concerning details of organization remain contingent on the action taken by those officials.

Mr. McNutt has held preliminary discussion with the appropriate people in Washington and has asked that the Health and Medical Committee proceed with the drafting of the legislation necessary for translating the objectives of the resolution into effective action.

This resolution was presented to the Health and Medical Committee at its meeting on July 2, 1941. The committee reviewed the resolution and voted to adopt it in principle and forward it to the Coordinator with the suggestion that he consult with the Secretary of War and the Secretary of Navy and that all matters concerning details of organization remain contingent on action taken by those officials. In August the Committee on Medical Preparedness of the American

Medical Association met in Washington with representatives of various governmental agencies to consider the proposal.

This resulted in a meeting of the Health and Medical Committee on October 22 to initiate the development of a Procurement and Assignment Service. At that meeting the following were present:

Health and Medical Committee.—Dr. Irvin Abell, Chairman; Surgeon General James C. Magee, U. S. Army; Admiral Ross T. McIntire, U. S. Navy; Surgeon General Thomas Parran, U. S. Public Health Service; Dr. Alfred N. Richards, Office of Scientific Research and Development; Dr. James A. Crabtree, Executive Secretary.

Liaison Officer.—Major Sam F. Seeley, M. C., U. S. Army.

Administrator and Staff.—Mr. Paul V. McNutt, Administrator; Mr. Watson B. Miller, Assistant Administrator; Mr. Leonard J. Calhoun, Assistant General Counsel; Mr. Perrin H. Lowrey, Office of General Counsel.

Consultants.—Dr. George Baehr, Office of Civilian Defense; Col. Leonard G. Rowntree, Selective Service; Dr. Frank H. Lahey, American Medical Association; Dr. Olin West, American Medical Association; Dr. Morris Fishbein, American Medical Association; Dr. Rosco G. Leland, American Medical Association; Dr. Fred W. Rankin, American Medical Association; Dr. Harvey B. Stone, American Medical Association; Dr. C. Willard Camalier, Subcommittee on Dentistry; Dr. Gerald T. Timmons, American Dental Association; Dr. C. Sidney Burwell, Subcommittee on Medical Education; Dr. Nathaniel W. Faxon, Subcommittee on Hospitals; Col. George F. Lull, M. C., U. S. Army; Dr. Hugo Mella, Veterans Administration; Dr. Verne K. Harvey, Civil Service Commission; Mr. George St. J. Perrott, National Institute of Health.

At this meeting, the Health and Medical Committee named a Commission to Draft a Program for a Procurement and Assignment Service, the members being Dr. Frank H. Lahey (Chairman), Dr. C. Sidney Burwell, Dr. Harvey B. Stone, Dr. Clarence D. Selby, Dr. Morris Fishbein and Dr. C. Willard Camalier.

At a meeting of the commission on October 28 the following report was made:

When the 1918 armistice was signed, the United States Army had 3,673,888 men in service and 31,501 Medical Corps officers. Should the United States Army be expanded for any reason in the near future to any similar size, at least an equivalent number of physicians would be required.

Today the United States Army includes approximately 90,000 officers, 6,000 nurses and 1,480,000 enlisted men. Of the 90,000 officers approximately 14,000 are in the medical department and of the soldiers approximately 109,000 are in the medical department. The officers in the medical department include 11,465 physicians in the Medical Corps, of whom 8,983 are reserve officers, 1,250 regular officers and 1,232 National Guard officers. Calculated on a basis of six medical officers per thousand men there is at present a shortage of about 1,473 medical officers. The Army Medical Department also includes 2,300 dentists in the Dental Corps and 660 veterinarians in the Veterinary Corps.

Should the Army not be greatly expanded within the next year but continue with a training program of about the present scope, a maximum of approximately 3,200 replacements would be required each year for the next five years during the period of the Selective Service Act. It is estimated that approximately two thirds of the physicians now in service would elect to remain for the period of the emergency. If, however, it should not be possible to retain these men in service, the number needed for replacement would be considerably expanded.

The Army has a Medical Reserve Corps which includes some physicians who can be called for various types of military service. In calling

men to service it is customary to call them from the Reserve Corps. Moreover, there are now organized a considerable number of sponsored units including general hospitals, field hospitals and smaller units. Today the so-called sponsored units include sixty-eight general hospitals, thirty evacuation hospitals and twenty-five surgical hospitals. These units are not yet an active part of the military establishment and the physicians associated with such units, if they are members of the Reserve Corps, may be called into service at any time. Then if these units are ordered into service, those physicians who are affiliated may be detached from the service to which they are assigned and returned to the sponsored unit.

THE NAVY

The needs of the United States Navy have been satisfied by a considerable expansion of the regular Navy Medical Service. The Navy demands about 6.5 physicians for every thousand of its personnel. At present enough physicians are enrolled to meet its needs, so that a new increment of approximately 100 physicians is required now as replacements. It seems likely that by July 1942 with the expansion of the Navy another 700 physicians would be required. To meet this need the Navy has a pool of 1,000 in its Reserve Corps.

The Navy also requires from 12 to 15 dentists each year. There are now 650 dentists on active duty, of whom 300 are dental reserves. The Navy has, moreover, approximately 1,500 dentists on reserve status.

THE PUBLIC HEALTH SERVICE

The United States Public Health Service requires about 35 new officers each year to meet its normal requirements for replacements. However, in view of the present expanded activities, the next year would require approximately 100 interns in public health service institutions. It also requires about 10 dentists each year in the form of new assignments and for replacements. At present the Public Health Service is recruiting physicians for defense areas, for service in extracantonment zones and for defense industries. Moreover, state health departments to meet new expansions require about 150 additional physicians.

The United States Public Health Service also maintains a reserve. Most of its men, however, are active in various state or local health positions. The removal of these men from such positions would, of course, require replacement.

THE UNITED STATES VETERANS BUREAU

The United States Veterans Bureau now has about 1,800 physicians in full time positions. About 500 of the physicians in the Veterans Bureau hold positions in the United States Army Medical Reserve Corps, as do also a considerable number of men in the field of public health either with local or with state organizations. In order to bring the Medical Reserve Corps of the Army into a position in which it could be counted as an active asset, all men holding reserve positions who are otherwise occupied in essential functions should resign their commissions from the United States Army Medical Reserve Corps.

THE CIVIL SERVICE COMMISSION

The Civil Service Commission provides many federal agencies with lists of physicians to meet their needs. Such agencies as the Indian Service, the Bureau of Mines, the Coast Guard Service, the Department of Pensions and many other groups employ physicians from the Civil Service lists. Altogether such agencies employ about 2,500 doctors. Each year they employ about 400 new men for replacements or for new positions. For the present fiscal year they lack 250 physicians to meet their requirements.

An evaluation of the total number of physicians immediately required to meet various governmental needs during the next year would indicate between 2,000 and 3,000 unless there should be a sudden expansion of the United States Army.

PRESENT CONDITIONS

At present even the United States Army Medical Department may have difficulty in securing physicians for its needs.

When the Selective Service age was changed from 35 to 28 the possibility of securing any considerable number of medical men by Selective Service was so greatly diminished as almost to eliminate the Selective Service as a source for securing physicians. The average age of graduation from medical school today is approximately 28 years. Following graduation the young physician must have an internship of at least one year in a recognized hospital. Many of the civilian hospitals of the country are already short of the number of interns that they require to carry on their service efficiently. Many of the large hospitals which employ considerable numbers of interns have established economy in the number of interns by reducing the number by one third to one half.

The medical schools of the United States graduate each year approximately 5,000 physicians. The number of physicians graduated is just about what is needed to supply the hospitals capable of extending the education of the young physician by an internship with the interns that they require. Many smaller hospitals having less than one hundred beds, which is the limit placed on an acceptable internship by the Council on Medical Education and Hospitals of the American Medical Association, find it difficult if not impossible to secure interns at this time. Indeed, such hospitals have become accustomed to paying fairly good salaries to young men, who then take a second or third year of training in the smaller hospitals. By the time the physician has completed his internship he is in many instances married. The estimates would indicate from one fourth to one half of the total number as being with dependents by the time they have finished the intern period. Moreover, among the physicians, as among the public generally, in view of the high physical standards maintained by the United States Army and Navy, slightly over one half of the young physicians are able to qualify physically for commissions in the Army or Navy Medical Corps. Indeed, it has been suggested that a different standard be maintained for physicians particularly as relates to minor defects of vision which are correctable with eyeglasses or to some similar defect in order to enable such physicians to be commissioned in the Medical Corps. In many instances these men

would be quite capable of giving good medical service without the likelihood that they would eventually become a dependent of the government.

In addition to the demands made on the medical profession by the services already mentioned, there is the necessity for some service related to civilian defense, to the Selective Service and to expanded war industries. Thus many of the large construction projects of both the Army and the Navy demand physicians who are being employed as contract physicians and surgeons for the period of the construction.

Moreover, in order to provide for a continuous supply of men with specialized training, approximately 800 to 1,000 of the young men who have completed one or two years of internship must take an additional three to five years of residency or specialistic training to qualify before the various boards which examine and certify men in the specialties.

SUMMARY

The coordination of the various demands made on the medical, dental and veterinary personnel with the available supply and the most efficient utilization of this professional personnel would seem to demand the establishment of a special agency capable of recording the qualified personnel available, of assigning such personnel or encouraging voluntary enlistment of such personnel in the services where most needed and of giving every qualified physician, dentist and veterinarian an opportunity to enroll himself in some service demanded by the national need.

CONCLUSION

For this reason a special committee, appointed by the Health and Medical Committee of the Office of Defense Health and Welfare Services has made the following recommendations:

1. That an Office of Procurement and Assignment of physicians, dentists, and veterinarians be established.

2. That this office shall function as part of the Office of Defense Health and Welfare Services, which is itself a part of the Office of Emergency Management.

3. The function of this office shall be to procure personnel from existing qualified members of the professions concerned. The office shall receive from various governmental and other agencies requests for medical, dental and veterinary personnel. These requests shall indicate the number of men desired, the time during which they must be secured, the qualifications and limitations placed on such personnel. The office must then by appropriate mechanism arrange to secure lists of professional personnel available to meet these requirements, utilizing such existing rosters, public and private, as it may find acceptable. It shall also be authorized to approach such professional personnel as is considered to be available and to use suitable means to stimulate voluntary enrollment.

4. The Office of Procurement and Assignment shall consist of a board of five members, one of whom shall be chairman. This board shall be chosen from members of the medical, dental or veterinary professions and shall not include any salaried employees of the federal government. This board shall function without salary but shall be entitled to actual and necessary transportation, subsistence and other expenses incidental to the performance of their duties.

5. The board shall appoint an executive secretary who shall serve also as executive officer and who shall be without vote in its deliberations and decisions. He shall serve as a full time employee with salary (to be determined) and with such assistants as the board may determine necessary to carry out its functions.

6. The board shall be authorized to establish such advisory committees and subcommittees as may be necessary. These committees shall represent the various interests concerned, such as medical, dental and veterinary schools, hospitals, Negro physicians and women physicians. Members of such committees shall serve without salary but shall be entitled to actual and necessary transportation, subsistence and other expenses incidental to the performance of their duties.

7. The board shall also be authorized to request various agencies of the government using medical, dental or veterinary personnel to appoint liaison officers and representatives to advise the board in carrying out its functions.

8. In carrying out its functions the board shall cooperate with such agencies as are now established under the Selective Service as well as other federal agencies.

On October 30 a letter was directed to the President by the Director of Defense Health and Welfare Services, as follows:

The coordination of the various demands made on the medical, dental and veterinary personnel of the nation and the most efficient utilization of this personnel would seem to require the establishment of a special agency capable of recording the qualified personnel available, of assigning or encouraging enlistment of such personnel in the services where most needed and of giving every qualified physician, dentist and veterinarian an opportunity to enroll himself in some service demanded by the national need.

For these reasons I wish to propose that there be established as one of the principal subdivisions of the Office of Defense Health and Welfare Services an office for the procurement and assignment of physicians, dentists and veterinarians. This office would be known as the Procurement and Assignment Agency.

The functions of the agency would be (1) to receive from various governmental and other agencies requests for medical, dental and veterinary personnel, (2) to secure and maintain lists of professional personnel available, showing detailed qualifications of such personnel, and (3) to utilize all suitable means to stimulate voluntary enrollment, having due regard for the overall public health needs of the nation, including those of governmental agencies and civilian institutions.

The agency would consist of a board of five members, one of whom would serve as chairman. The board would serve without salary but would be entitled to actual and necessary transportation, subsistence and other expenses incidental to the performance of its duties.

A full time executive officer (with salary to be determined) would be appointed, together with such assistants as would be required to carry out the functions of the Agency.

I recommend that the board be composed of Dr. Frank Lahey, chairman, Dr. James Paullin, Dr. Harvey B. Stone, Dr. Harold S. Diehl and Dr. C. Willard Camalier.

This communication is addressed to you in accordance with provisions contained in paragraph 4 of the Executive Order, dated Sept. 3, 1941, "Establishing the Office of Defense Health and Welfare Services in the Executive Office of the President and Defining Its Functions and Duties," to the effect that the President shall approve the establishment of the principal subdivisions of the Office of Defense Health and Welfare Services and the appointment of the heads thereof.

In the event you approve the establishment of the Procurement and Assignment Agency, together with the board membership as recommended, I shall proceed immediately with the creation of the agency and will prepare budget estimates in the amount of approximately \$50,000 for submission to the Budget Bureau to cover the costs of the agency.

In addition I would propose to instruct the Agency to draft legislation which may be necessary to submit to the Congress providing for the involuntary recruitment of medical, dental and veterinary personnel, in the event the exigencies of the national emergency appear to require it.

PAUL V. McNUTT.

The President wrote Approved on this letter. The initial meeting of the Board of the Procurement and Assignment Service was held on November 6 in Washington. A subsequent meeting was held on November 26, and at these meetings the organization was developed as follows:

BOARD OF PROCUREMENT AND ASSIGNMENT SERVICE

Dr. Frank H. Lahey, Chairman, President, American Medical Association, Boston.

Dr. C. Willard Camalier, Chairman, Dental Preparedness Committee, American Dental Association, Washington, D. C.

Dr. Harold S. Diehl, Dean, Medical Sciences, University of Minnesota, Minneapolis.

Dr. James E. Paullin, Atlanta, Ga.

Dr. Harvey B. Stone, Associate Professor of Surgery, Johns Hopkins University School of Medicine, Baltimore.

Dr. Sam F. Seeley, Executive Officer.

COMMITTEE ON DENTISTRY

Dr. John T. O'Rourke, Chairman, Dean, Dental School, University of Louisville, Louisville, Ky.

Dr. Leroy M. S. Miner, Dean, Dental School, Harvard University, Boston.

Dr. Frederick B. Noyes, Chicago.

Dr. Guy S. Millberry, Los Gatos, Calif.

Dr. B. K. Westfall, Indianapolis.

COMMITTEE ON HOSPITALS

Dr. Winford H. Smith, Chairman, Director, Johns Hopkins Hospital, Baltimore.

Dr. Nathaniel W. Faxon, Director, Massachusetts General Hospital, Boston.

Dr. Claude W. Munger, Director, St. Luke's Hospital, New York.

Dr. M. T. MacEachern, Associate Director, Americal College of Surgeons, Chicago.

Rev. Alphonse M. Schwitalla, S.J., Dean, St. Louis University School of Medicine, St. Louis.

COMMITTEE ON INDUSTRIAL HEALTH AND MEDICINE

Dr. C. D. Selby, Chairman, Medical Director, General Motors Corporation, Detroit.

Dr. A. J. Lanza, Assistant Medical Director, Metropolitan Life Insurance Company, New York.

Mr. William Yant, Director of Research and Development, Mine Safety Appliance Company, Pittsburgh.

Dr. Lloyd Noland, Chief Surgeon, Tennessee Coal, Iron and Railroad Company, Fairfield, Ala.

Prof. Philip Drinker, Department of Industrial Hygiene, School of Public Health, Harvard University, Boston.

Dr. George M. Smith, Department of Anatomy, Yale University School of Medicine, New Haven, Conn.

Dr. E. C. Holmblad, Chicago.

COMMITTEE ON MEDICAL EDUCATION

Dr. C. Sidney Burwell, Chairman, Dean, Harvard University Medical School, Boston.

Dr. Willard C. Rappleye, Dean, College of Physicians and Surgeons, Columbia University, New York.

Dr. John H. Musser, Professor of Medicine, Tulane University School of Medicine, New Orleans.

Dr. William S. Middleton, Dean, University of Wisconsin Medical School, Madison.

Dr. Loren R. Chandler, Dean, Stanford University School of Medicine, San Francisco.

COMMITTEE ON NEGRO HEALTH

Dr. M. O. Bousfield, Chairman, Director of Negro Health, Julius Rosenwald Fund, Chicago.

Dr. Russell A. Dixon, Dean, College of Dentistry, Howard University, Washington, D. C.

Dr. A. N. Vaughn, Surgeon, Homer G. Phillips Hospital, St. Louis.

Dr. G. Hamilton Francis, Norfolk, Va.

Mr. A. W. Dent, Superintendent, Flint Goodridge Hospital, New Orleans.

COMMITTEE ON PUBLIC HEALTH

Dr. Carl V. Reynolds, Chairman, Raleigh, N. C.

Dr. Gaylord West Anderson, University of Minnesota, Minneapolis.

Dr. Waller S. Leathers, Vanderbilt University School of Medicine, Nashville, Tenn.

Dr. Harry S. Mustard, New York.

Dr. John L. Rice, New York.

COMMITTEE ON VETERINARY MEDICINE

Dr. J. G. Hardenbergh, Chairman, Executive Secretary, Veterinary Medical Association, Chicago.

Dr. Harry W. Jakeman, President, Veterinary Medical Association, Boston.

Dr. John R. Mohler, Chief, Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

Dr. William A. Hagan, Dean, Cornell University College of Veterinary Medicine, Ithaca, N. Y.

Dr. Cassius Way, New York.

COMMITTEE ON WOMEN PHYSICIANS

Dr. Sara Murray Jordan, Chairman, Boston.

Dr. Ruth Evelyn Boynton, University of Minnesota, Minneapolis.

Dr. Margaret D. Craighill, Dean, Women's Medical College of Pennsylvania, East Falls, Philadelphia.

Dr. Alice Hamilton, Hadlyme, Conn.

Dr. Irma Jackson, Forest Hills, L. I., N. Y.

Dr. Ada Chree Reid, New York.

COMMITTEE ON INFORMATION

Dr. Morris Fishbein, Chicago, Chairman.

Mr. J. J. Bloomfield, Sanitary Engineer, U. S. Public Health Service, National Institute of Health, Bethesda, Md.

Dr. John F. Fulton, Yale University School of Medicine, New Haven, Conn.

Dr. Richard M. Hewitt, Mayo Clinic, Rochester, Minn.

Dr. Ira V. Hiscock, Yale University School of Medicine, New Haven, Conn.

Dr. Sanford V. Larkey, Division of Medical Sciences, National Research Council, Washington, D. C.

Dr. Robert N. Nye, Managing Editor, New England Journal of Medicine, Boston.

Consultants will be appointed to the Service, as required.

The following liaison officers have been designated by the federal agencies concerned:

Capt. Paul A. Paden, M. C., U. S. Army, Washington, D. C.

Capt. P. M. Allbright, Medical Officers Reserve Section, U. S. Navy, Washington, D. C.

Asst. Surg. Gen. Paul M. Stewart, U. S. Public Health Service, Washington, D. C.

Dr. Hugo Mella, Veterans Administration, Washington, D. C.

Lieut. Col. C. G. Parker Jr., Selective Service System, Washington, D. C.

Dr. Verne K. Harvey, U. S. Civil Service Commission, Washington, D. C.

Dr. George Baehr, Medical Director, Office of Civilian Defense, Washington, D. C.

Dr. Edwin F. Daily, Director, Division of Health Services, Children's Bureau, Washington, D. C.

DEFINITION OF PURPOSE

The primary objective of the Procurement and Assignment Service is to maintain a complete list of all physicians, dentists and veterinarians of the entire country with detailed information as to age, physical condition, professional qualifications and availability for service in the various military, civil and industrial agencies of the country. This information is to be made available to all these groups who desire to enlist the services of these professional men.

PLAN OF OPERATION

The existing facilities of the American Medical Association, American Dental Association and American Veterinary Medical Association have been graciously offered to the Procurement and Assignment Service. A regional office has been set up in Chicago in which questionnaires, rosters and punch card data pertaining to all physicians, dentists and veterinarians will be maintained and kept up to date. The Committees on Medical Preparedness of the American Medical Association, American Dental Association and American Veterinary Medical Association will be utilized in the conduct of surveys, dissemination of information to the professions and the recruitment of personnel as requisitioned by various governmental agencies. The Procurement and Assignment Service will maintain a central office in Washington, D. C. The regional office in Chicago will maintain the rosters. A board in each of the nine corps areas will consist of representatives of medical education, hospitals, the Medical Preparedness Committee of the American Medical Association and two civilian practitioners in each corps area. These boards will act in an advisory capacity with the view of assuring adequate professional care of the civilian and industrial populations within the area and in the selection of those professional people within the area who can be spared for service with the armed forces. They will function through the existing state, district and county committees on medical preparedness. The medical, dental and veterinary medical needs will be considered by committees of each of the respective professions.

After a complete survey has been made and the availability of personnel has been determined, the central office will then be prepared to furnish to all requisitioning agencies rosters of those available for duty within their organizations. The result of questionnaires clearly indicates that large numbers of physicians, dentists and veterinarians will voluntarily make themselves available for positions which will guarantee adequate professional care to the civil, industrial and military requirements. It is planned that in the very near future every physician, dentist and veterinarian will receive a questionnaire from the Procurement and Assignment Service on which he will be asked to designate his preference regarding the capacity in which he desires to contribute his maximal efforts to the successful culmination of the present national emergency. Alternate preferences will be stated and every professional man will be certified by the Procurement and Assignment Service as having volunteered his services.

From rosters maintained as a result of the foregoing information, requisitioning agencies will be furnished the names of those available as the needs arise, should expansion of the defense program require additional professional personnel. This plan is designed primarily to assure adequate personnel for the armed services and to avoid unwarranted dislocation of professional people from their present localities.

ASSIGNMENT

Rosters maintained by the Procurement and Assignment Service will be made available to all agencies requiring professional personnel. These agencies will submit requests to the Procurement and Assignment Service indicating the number and qualifications of men desired and the time during which they must be procured. These agencies will then be furnished lists of men who have been determined to meet their needs. Notification will be transmitted to these people by the Procurement and Assignment Service or by the agency to which the lists have been furnished.

This service will be available to all federal, state, industrial and civil agencies of the country. The following agencies have been represented in the initial meetings of the Procurement and Assignment Service: Army, Navy, U. S. Public Health Service, Veterans Administration, Civil Service, Office of Civilian Defense, Selective Service, Children's Bureau and Bureau of Animal Industry.

The industrial needs will be determined by the Committee on Industrial Health and Medicine.

Federal, state and county health department needs will be determined by the Committee on Public Health.

The need for women physicians will be determined by the Committee on Women Physicians.

The need for Negro physicians will be determined by the Committee on Negro Health.

The Committee on Hospitals will consider the needs of all hospitals with a view to maintaining an adequate number of staff members, interns, residents and instructors.

The Committee on Medical Education will consider the needs of medical schools from the standpoint of teaching, staffs, research facilities, and so on.

The dental and veterinary committees will survey their respective professions with a view of assuring proper disposition of members of these professions throughout the country.

DISSEMINATION OF INFORMATION

The Committee on Information is charged with the responsibility of disseminating information to all physicians, dentists and veterinarians in order that they may be kept informed of the progress of their Procurement and Assignment Service. This will be done by all available means of communication; viz. national and state medical journals, who will be kept informed of the progress. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has offered its services in the form of a section on the Procurement and Assignment Service, where progress of the service will be reported and a current list of the needs of the various services will be maintained, together with a report on the progress of the assignment of personnel to meet these needs.

The Procurement and Assignment Service has begun to function and the following status of requisitioning agencies has been determined:

Army.—The present allotment by the War Department of Medical Department officers as of October 31 is: Medical Corps 12,938, Dental Corps 2,911, Veterinary Corps 689. As of October 31 there were on active duty: Medical Corps 11,439, Dental Corps 2,905, Veterinary Corps 720. This leaves a shortage of "filler" replacements, as follows: Medical Corps 1,499, Dental Corps 6, Veterinary Corps none. At the present time there are sufficient Dental Corps Reserve Officers and Veterinary Corps officers to fill the present and the immediate anticipated needs. The Medical

Reserve Corps has been practically depleted, although there are many medical reserve officers who have not been called to active duty. These reserve officers are engaged in the completion of internships, are employed in positions essential to defense efforts, in a civilian capacity, or are enrolled in affiliated units which would be called to active duty in case of war. When a sufficient number has entered the service on active duty to meet the "filler" requirements, additional commissions will result in the release of those officers now on active duty who have undergone their period of training, but whose release is dependent on replacement.

On October 27 publication of an Army regulation pertaining to commissioning of officers in the Army provided for the commissioning of officers in the Medical Corps in ranks from First Lieutenant to Colonel on authority of the Secretary of War. Commissions will not be granted hereafter in the Reserve Corps but will be in the "Army of the United States." Available reserve corps officers will be utilized before those commissioned in the "Army of the United States." This regulation provides that officers commissioned in the Army of the United States will be called to immediate active duty and will be discharged from their commissions not later than six months after termination of the national emergency. This provision of immediate active duty does not apply to commissions in the Army of the United States of junior and senior medical students, twelve month interns or officers associated with affiliated units. Hereafter appointments of third and fourth year medical students will be in the Medical Administrative Corps of the Army of the United States, and appointments after graduation from medical school will be in the Medical Corps of the Army of the United States. It should be emphasized that these officers will not be called to active duty until they have completed twelve months of internship.

At the present time, with an army of 1,700,000, the Medical Department has been fortunate in that large numbers of senior officers with World War experience who have continued their services since that time are available for assignment to important positions. As a result there are no vacancies at the present time in the grades of Colonel or Lieutenant Colonel and very few vacancies in the grade of Major or Captain. This, therefore, under the present strength of the Army, calls for a large number of commissions in the Medical Corps in the junior grades. It must be borne in mind, however, that should an expansion take place large numbers of officers in senior as well as junior grades will be required. If expansion occurs, those officers now on duty who are qualified for higher grades will be promoted and officers commissioned in the Army of the United States will be commissioned in the grade that will fill the requirements.

Navy.—Medical Corps: By June 1942 the Navy will require 700 additional medical officers. It is anticipated that these needs will be filled by the commission of those completing internship and those now in the Reserve. In the Dental Corps at present there is an adequate number in the Reserve Corps to meet the anticipated needs of the near future.

Veterans Administration.—Physicians: At present there is an acute shortage of 100 physicians. The immediate need is for 100 associate physicians with

Civil Service qualifications in the following fields: tuberculosis, 2; neuropsychiatry, 40; general medicine and surgery, 40; eye, ear, nose and throat, 5; roentgenology, 3; pathology, 4; urology, 2; orthopedics, 2; cardiology, 1; chest surgery, 1. For the fiscal year ending June 30, 1942 the total number of physicians required under present needs is 210. Twelve dentists are needed for this period. For the fiscal year 1943, 300 additional physicians will be required.

The needs of the Veterans Administration will increase in direct proportion to the number of patients transferred from the active military forces to the Veterans Administration during the present defense program. At the present time patients who are disabled in the military service are transferred to the Veterans Administration. As the defense program progresses, greater numbers will be transferred. The expansion will be followed carefully by the Procurement and Assignment Service, and the needs of the Veterans Administration will be transmitted to the Procurement and Assignment Service as they arise.

Public Health.—Physicians: One hundred medical officers are needed prior to Jan. 1, 1942 and approximately 150 more by June 30, 1942. About 10 new dental officers will be required by the next calendar year.

Civil Service.—Physicians: Approximately 500 physicians will be required prior to July 1, 1942. The needs for dental and veterinary personnel will be reported to the Procurement and Assignment Service as they arise.

The needs for the Office of Civilian Defense, the Selective Service and the state and local health departments parallel the needs of the civil populations, and satisfactory functioning of these agencies will depend a great deal on the appropriate allocation of professional personnel to the civil population.

Under authority of an executive order dated September 3, establishing the Office of Defense Health and Welfare Services, that office was charged with the duty to "serve as the center for the coordination of health and welfare services made available by the departments and agencies of the federal government and other agencies, public and private, to meet the needs of state and local communities arising from the defense program and take necessary steps to secure the cooperation of the appropriate federal departments and agencies relative thereto." The Procurement and Assignment Service, under the Office of Defense Health and Welfare Services, has been charged with the coordination of medical, dental and veterinary personnel for the armed services with the view of assuring adequate care of the civil and industrial population. This program represents a concerted effort on the part of every physician, dentist and veterinarian in the country, and the success of the service is assured because of their indicated willingness to serve in the national emergency. With the knowledge that the Procurement and Assignment Service will coordinate the demands of the defense program so as to minimize disruption of the present care of the civil population and the dislocation of professional people from their present localities, it is anticipated that enrolment in the various fields of endeavor by professional men will be excessive and that the carrying out of the duties of the Procurement and Assignment Service will be facilitated by the unselfish cooperation of all concerned.

ADDITIONAL LIST OF PRIORITIES AMONG HEALTH SUPPLIES

A letter from Donald M. Nelson, Director of Priorities, Office of Production Management, Washington, D. C., calls attention to preference rating order P-29, together with amendment 1 (dated October 7) to this order, which provides for a rating of A-10 for manufacturers of the health supplies listed in the order. Through this assistance, physicians should be able to secure necessary supplies and equipment from their usual sources, if their suppliers have taken advantage of the assistance made available through this order. Twelve important additions to the list of health supplies to the manufacturer of which A-10 preference rating is available have been made.

The original list, issued with the announcement of the Health Supplies Rating Plan on August 25 and published in *THE JOURNAL*, September 27, page 1103, contained fourteen classifications. Several of these have been extended to include more items, in addition to the new classifications set up in the amendment to Preference Rating Order P-29.

The complete health supplies list, which now covers twenty-five classifications for medical, surgical, dental and veterinarian use, follows. Those classifications marked with an asterisk are new, and items in italics are extensions of classifications set up in the original list.

- * 1. Acoustical aids.
- 2. Anesthesia apparatus and supplies.
- * 3. Atomizers (medical use only).
- 4. Biologicals, antitoxins, serums, *sterile ampules and intravenous solutions.*
- 5. Clinical thermometers.
- 6. Diagnostic equipment and *supplies.*
- * 7. Hospital carts, racks and charts.
- 8. Hypodermic syringes and needles.
- * 9. Infant incubators.
- 10. Instruments.
- * 11. Invalid chairs, walkers and crutches.
- 12. Laboratory equipment and supplies.
- 13. Medicinal chemicals (limited to medical use only).
- 14. Operating room *supplies* and equipment.
- * 15. Ophthalmic products and instruments.
- * 16. Physical therapy equipment (limited to medical use only).
- * 17. Respirators, resuscitators and iron lungs.
- 18. Rubber hospital sundries.
- * 19. Sickroom furniture, equipment and supplies.
- * 20. Splints and fracture equipment.
- 21. Sterilizers, *blanket and solution warmers.*
- 22. Surgical dressings and adhesive plasters.
- * 23. Surgical and orthopedic appliances (including artificial limbs and arms).
- * 24. Sutures and suture needles.
- 25. X-ray equipment and supplies.

A manufacturer of any of these items wishing to avail himself of the assistance offered by this plan should make written application to the Health Supplies Section, Office of Production Management, Washington, D. C., for form PD-79, "Report of Requirements for Scarce Materials," and at the same time file a complete catalogue showing as nearly as possible all the finished articles he manufactures.

Amendment 1 to Preference Rating Order P-29

Paragraph (a) (2) is hereby amended to read as follows:

(2) "Health Supplies" means such of the following items as are to be produced by the producer for medical, surgical, dental or veterinarian uses:

- 1. Acoustic aids.
 - 2. Anesthesia apparatus and supplies.
 - 3. Atomizers (medical use only).
 - 4. Biologicals, antitoxins, serums, sterile ampules and intravenous solutions.
 - 5. Clinical thermometers.
 - 6. Diagnostic equipment and supplies.
 - 7. Hospital carts, racks and charts.
 - 8. Hypodermic syringes and needles.
 - 9. Infant incubators.
 - 10. Instruments.
 - 11. Invalid chairs, walkers and crutches.
 - 12. Laboratory equipment and supplies.
 - 13. Medicinal chemicals (limited to medical use only).
 - 14. Operating room supplies and equipment.
 - 15. Ophthalmic products and instruments.
 - 16. Physical therapy equipment (limited to medical use only).
 - 17. Respirators, resuscitators and iron lungs.
 - 18. Rubber hospital sundries.
 - 19. Sickroom furniture, equipment and supplies.
 - 20. Splints and fracture equipment.
 - 21. Sterilizers, blanket and solution warmers.
 - 22. Surgical dressings and adhesive plasters.
 - 23. Surgical and orthopedic appliances (including artificial limbs and arms).
 - 24. Sutures and suture needles.
 - 25. X-ray equipment and supplies
- and such additional items as may be added to the foregoing from time to time by order of the Director of Priorities.

The manufacturers of research laboratory supplies and equipment have also been granted assistance through preference rating order P-43, to which reference was made in *THE JOURNAL*, October 18, page 1365.

PROGRESS IN CIVILIAN DEFENSE ORGANIZATION

Emergency medical service for civilian defense is developing according to plans laid down by the Medical Division of the Office of Civilian Defense in its Bulletin No. 1 (*THE JOURNAL*, August 30, p. 783). A roll call made during Civilian Defense Week, November 10-16, showed that nineteen states and the District of Columbia had appointed state chiefs of emergency medical service up to that date. A total of four hundred and seventy-eight city and county governments had local chiefs of emergency medical service. Massachusetts, New York, Pennsylvania and Vermont led in these appointments. Thirty states have designated chairmen of the health and medical committees of their state defense councils; in some cases these men are also the state chiefs of emergency medical service. Following the recommendations of the Medical Division, three hundred and eighty-three hospitals have organized emergency medical field units and twenty-four such units have been organized outside of hospitals. Seventy-three of the units are located in New York State.

The Volunteer Nurse's Aide training program was reported to be under way in sixty-one Red Cross chapters, with one hundred and seventy-seven hospitals participating. The roll call showed that three hundred and forty-three aides had completed the course and had already given more than eight thousand hours of service.

MEDICAL AID TO RUSSIA AND NORWAY

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York, has approved sending medical and surgical aid to Russia in collaboration with established relief agencies, it was announced by Mrs. Rogers Balcom, executive chairman. In response to special appeals, quantities of sulfapyridine tablets and stainless steel Michel forceps are being assembled by the committee for use in Russian hospitals. During the past week a special request was received from the Free Norwegians in Iceland for two thousand, three hundred and thirty-six assorted instruments, 10 pounds of sulfapyridine powder for sprinkling on wounds and twenty-four physicians' first aid sets. These supplies will be used to help equip four mobile units of fifty bed capacity.

HELIUM PRODUCTION INCREASED

The helium plant operated by the U. S. Bureau of Mines at Amarillo, Texas, stepped up the production of helium last year to more than 16½ million cubic feet of this noninflammable gas, of which 15 million cubic feet was used by the government for defense and military purposes. During the last fiscal year more wells have been driven and the plant has been expanded, which it is expected will increase the capacity of helium production to about 36 million cubic feet annually. This, according to the U. S. Department of the Interior, is the only helium plant in the world.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, which comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

ABRAMSON, Milton, Captain, Minneapolis, Fort Leonard Wood, Mo
BAKER, Joseph Harrison, Captain, LaCrosse, Kan, Corps Area Service Command Station Hospital, Fort Riley, Kan
BASSETT, Wallace Herman, 1st Lieut, Texarkana, Ark, Corps Area Service Command Station Hospital, Camp J. T. Robinson Ark
COWAN, George Morterud, 1st Lieut, Knoxville, Iowa, Corps Area Service Command Induction Station, Fort Leavenworth, Kan
DALTON, Marvin Lewis, 1st Lieut, Brinkley, Ark, Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark
DISHONGH, Howard Allen, 1st Lieut, Little Rock, Ark, Camp J. T. Robinson, Ark
FRICK, John Paul, Lieut Colonel, Kansas City, Mo, Fort Leonard Wood, Mo
HALPERIN, Philip Harold, 1st Lieut, Kansas City, Mo, Corps Area Service Command Station Hospital, Fort Leavenworth, Kan
HANCHEY, Carl Cecil, 1st Lieut, DeQueen, Ark, Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark
KEIL, Marcus Augustine, 1st Lieut, Thompson, Iowa, Corps Area Service Command Induction Station, Camp J. T. Robinson, Ark
KIPEN, Charles Samuel, 1st Lieut, St. Louis, Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark
LARSON, Ralph Hertrich, 1st Lieut, Tenney, Minn, Corps Area Service Command Station Hospital, Fort F. E. Warren, Wyo
LEUTHER, Peter Alfred, 1st Lieut, Mankato, Minn, Fort Riley, Kan
MARKS, Roger Weston, 1st Lieut, St. Paul, Fort Riley, Kan
MEAD, Louis Czosnyka, Major, Minneapolis, Cal Aero Training Corporation, Grand Central Air Terminal, Glendale, Calif
NEUFELD, Robert John, 1st Lieut, Davenport, Iowa, Rock Island Arsenal, Rock Island, Ill
PETERS, Claude Frederick, 1st Lieut, Benton, Ark, 217th General Hospital, Fort Riley, Kan

NINTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Ninth Corps Area, which comprises the states of Washington, Montana, Oregon, Nevada, Utah, California and Idaho:

ANDERSON, Murl O, Captain, Hardin, Mont, Third Division, Fort Lewis, Wash
ANDREWS, Harry H., 1st Lieut, Sumner, Wash, Fort Stevens, Ore
BAISINGER, Leo P., 1st Lieut, Bakersfield, Calif, Fort Ord, Calif
BARBOUR, Nathan P., Lieut Colonel, Lockeford, Calif, Camp Cooke, Lompoc, Calif
BOLTON, Leslie T., Lieut Colonel, Reno, Nev, Fort Winfield Scott, Calif
BURLESON, Ferris C., 1st Lieut, San Jose, Calif, Station Hospital, Camp Roberts, Calif
CAWLEY, John J., 1st Lieut, Bakersfield, Calif, Office of Corps Area Surgeon pending assignment to Hawaiian Department
CHOY, Frank Jue, 1st Lieut, San Francisco, Camp Grant, Ill
DEINE, Edward J., 1st Lieut, Coquille, Ore, Fort McDowell, Calif
DITTES, Albert G., 1st Lieut, Glendale, Calif, 808th Engineer Battalion (Aviation), March Field, Calif
EFFRON, Morton, 1st Lieut, Los Angeles, Camp Callan, Calif
FAGLESTON, John R., 1st Lieut, Santa Monica, Calif, Station Hospital, Fort Ord, Calif
FRIBORG, Arnold L., 1st Lieut, Brief, Wash, Station Hospital, Fort Lewis, Wash
GALLAGHER, Hiram, Captain, San Anselmo, Calif, Camp Seeley, Calif
JOHNSON, George H., 1st Lieut, Vancouver, Wash, Fort Lawton, Wash
JONAS, Carl H., 1st Lieut, Medical Lake, Wash, Camp Haan, Calif
KIMURA, Jiro, 1st Lieut, Berkeley, Calif, Medical Replacement Center, Camp Grant, Ill
LLI, Gilbert 1st Lieut, Los Angeles, 58th Quartermaster Regiment, Stockton, Calif
LEVITT, Louis, 1st Lieut, Worden, Mont, 183d Field Artillery, Fort Francis F. Warren, Wyo
LFWF, Irving A., 1st Lieut, Los Angeles, Camp Roberts, Calif
LOMAS, Max I., 1st Lieut, Los Angeles, 3d Coast Artillery, Fort McArthur, Calif
MARKS, Roland T., Captain, Hillsborough, Calif, Fort Winfield Scott, Calif

REYNOLDS, Garland Alexander, 1st Lieut, Cape Girardeau, Mo, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
SCHMIDT, John Henry, 1st Lieut, Cheyenne, Wyo, Corps Area Service Command Station Hospital, Fort F. E. Warren, Wyo
SCORSE, Sidney William, 1st Lieut, Webb City, Mo, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
SIGURDSSON, Jon Olafur Stefan, 1st Lieut, West Fargo, N. D., Corps Area Service Command Station Hospital, Fort Snelling, Minn
SILVERBERG, Charles, 1st Lieut, Richmond Heights, Mo, Fort Leonard Wood, Mo
SIMPSON, Ronald Albert, 1st Lieut, Hutchinson, Kan, Corps Area Service Command Station Hospital, Fort Des Moines, Iowa
SMAZAL, Stanley Francis, 1st Lieut, Davenport, Iowa, Engineer Replacement Center Infirmary, Fort Leonard Wood, Mo
STAUFFER, Harry Beach, Major, Jefferson City, Mo, Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark
STOCKER, William James, 1st Lieut, Fort Smith, Ark, Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark
WASHBURN, Arthur Mansfield, Lieut Col, Little Rock, Ark, Fort Jackson, S. C.
WICKS, William Jeremiah, 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Fort Riley, Kan
WINDMILLER, Myrl Eugene, 1st Lieut, Kansas City, Mo, Corps Area Service Command Station Hospital, Fort Riley, Kan

Orders Revoked

HEDEMARK, Homer Harold, Captain, Thief River Falls, Minn, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo

Relieved from Active Duty

GINSBERG, William, Major, St. Paul, Fort Snelling, Minn
SPIRY, Arthur William, 1st Lieut, Moberg, S. D., Fort Riley, Kan
STICKLER, Ralph O., 1st Lieut, Kirksville, Mo, Jefferson Barracks, Mo
THOMPSON, Carl Oliver, 1st Lieut, Hendricks, Minn, Fort Snelling, Minn
VAN VALKENBURG, John Donald, 1st Lieut, Floodwood, Minn, Fort Snelling, Minn
YELLEN, Benjamin Louis, 1st Lieut, Wadsworth, Kan, Fort Riley, Kan

MEYER, Vincent S., 1st Lieut, Los Altos, Calif, Camp Sibert, Calif
MIYAUCHI, Yukio, 1st Lieut, Santa Maria, Calif, Camp Grant, Ill
NEWTON, Abram M., Major, Pocatello, Idaho, Station Hospital, Fort Lewis, Wash
O'CONNOR, Michael J., 1st Lieut, San Mateo, Calif, Camp Callan, Calif
ROSSITER, Stanford B., 1st Lieut, San Francisco, Camp Seeley, Calif
RUDEN, S. J., 1st Lieut, Eureka, Calif, Fort Worden, Wash
SAWYER, Harry W., Jr., 1st Lieut, Fallon, Nev, 216th Const Artillery, Camp Haan, Calif
SHEAFE, Earle V., Lieut Colonel, Oakland, Calif, Station Hospital, Fort Ord, Calif
SHUMAN, John W., Lieut Colonel, Santa Monica, Calif, Fort Ord, Calif
SOUTH, Francis Floyd, Major, Portland, Ore, Fort Stevens, Ore
STOCKTON, Christopher, 1st Lieut, Bakersfield, Calif, Third Army Corps, Presidio of Monterey, Calif
ST. PIERRE, Roderick G., Captain, Portland, Ore, Fort Stevens, Ore
STROUSE, Carl D., 1st Lieut, Hollywood, Calif, 41st Division, Fort Lewis, Wash
TALBOT, John C., 1st Lieut, Berkeley, Calif, Induction Station, Portland Recruiting District, Portland, Ore
TOMA, John J., 1st Lieut, Los Angeles, Fort Rosecrans, Calif
WARD, Henry C., 1st Lieut, Long Beach, Calif, Station Hospital, Camp Roberts, Calif
WAITS, Floyd J., 1st Lieut, Sebastopol, Calif, Camp Roberts, Calif
WILCON, Charles F., Major, Los Angeles, Camp San Luis Obispo, Calif
WILSON, Kent R., Captain, Santa Barbara, Calif, Camp Roberts, Calif

Orders Revoked

ARNOWITZ, Isaac, 1st Lieut, San Francisco
CHAMPOUX, Clement G., 1st Lieut, Selah, Wash, Camp Clatsop, Ore
DAGGETT, Gilbert G., 1st Lieut, Madera, Calif, Fort Worden, Wash
LDFLSON, Zandy C., 1st Lieut, Portland, Ore
FREDRICKSON, Clyde H., Lieut Col, Missoula, Mont
RUKKE, Raymond V., 1st Lieut, Monterey, Calif
SCHADE, George H., 1st Lieut, Camp Haan, Calif

Relieved from Active Duty

PETERFY, Richard A., Captain, Camp San Luis Obispo, Calif
PORTER, James L., 1st Lieut, Camp McQuaide, Calif

Resignation

ONFILI, Thomas J., 1st Lieut, Fort Rosecrans, Calif

ORDERED TO FOREIGN DUTY

GRFLN, Arthur Morton, 1st Lieut, Station Dispensary, Allbrook Field, Canal Zone
HTRMFS, Richard Lawrence, 1st Lieut, Ponce Puerto Rico, Flight Surgeon's Office, Borinquen Field, Puerto Rico
JACOB, Samuel Sprick, III, Captain, Corozal, Canal Zone

MANGINELLI, Samuel Thomas, 1st Lieut, 70th Medical Battalion, Corozal, Canal Zone
MOSIMAN, William Dillon, 1st Lieut, Morton, Ill, Headquarters, Philippine Department, Fort San Marcos, Manila

ORGANIZATION SECTION

OFFICIAL NOTES

FOURTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Arrangements have been largely completed for the fourth annual Congress on Industrial Health sponsored by the American Medical Association, which will be held Monday and Tuesday, Jan. 12-13, 1942, at the Palmer House in Chicago. These meetings are open to physicians and others interested in industrial health. There is no registration fee. Topics and speakers are as follows:

OPENING SESSION, MONDAY, 9:45 A. M.

Report of the Council on Industrial Health

STANLEY J. SEEGER, M.D., Chairman, Texarkana, Texas.

Procurement and Assignment of Physicians in Industry

(Speaker to be announced)

Lecture on Industrial Medicine.

Tuberculosis in Industry—A Résumé.

LEROY U. GARDNER, M.D., Saranac Lake, N. Y.

Director, the Saranac Laboratory for the Study of Tuberculosis

The Physiology of Work

A. C. IYV, M.D., Chicago

Professor of Physiology, Northwestern University School of Medicine.

Medical Aspects of Vocational and Industrial Training

W. A. SAWYER, M.D., Rochester, N. Y.

Chairman, Committee on Industrial Health, Section on Preventive and

Industrial Medicine and Public Health, American Medical Association

Red Lacquer Room

MONDAY AFTERNOON, 2:30

A Dental Program for Industry

R. M. WALLS, D.D.S., Bethlehem, Pa.

Chairman, Committee on Economics, American Dental Association.

Industrial Dermatoses.

A Report by the Committee on Industrial Dermatology, Section on

Dermatology and Syphilology, American Medical Association

C. GUY LANE, M.D., Chairman, Boston

CHARLES C. DENNIE, M.D., Kansas City, Mo.

JOHN G. DOWNING, M.D., Boston.

HARRY FOERSTER, M.D., Milwaukee

EDWARD A. OLIVER, M.D., Chicago

MARION SULZBERGER, M.D., New York

The Panel System in Workmen's Compensation Administration.

DAVID J. KALISKI, M.D., New York

Director, Committee on Workmen's Compensation, Medical Society of

the State of New York.

Mass X-Ray Surveys—Evaluation of Technique and Equipment

MAJOR ALFRED A. DE LORIMIER, M.C., Washington, D. C.

Director, Department of Roentgenology, Army Medical School

Red Lacquer Room

MONDAY AFTERNOON, 2:30

SYMPOSIUM ON UNDERGRADUATE INDUSTRIAL MEDICAL EDUCATION

Present Problems in Curriculum Adjustment

WILLIAM D. CUTTER, M.D., Chicago

Secretary, Council on Medical Education and Hospitals, American

Medical Association

Industrial Health—A Separate Discipline

T. LYLE HAZLETT, M.D., East Pittsburgh, Pa.

Professor of Industrial Hygiene, University of Pittsburgh School of

Medicine.

Coordination of Industrial Hygiene with Clinical Teaching

DOUGLAS E. CUMMINGS, Denver

Director, Division of Industrial Hygiene, University of Colorado School

of Medicine and Hospitals

The Industrial Clinical Clerkship

FRED J. WAMPLER, M.D., Richmond

Professor of Preventive Medicine, Medical College of Virginia

Industrial Experience in the Internship

WILL F. LYON, M.D., Chicago

Assistant Professor of Surgery, University of Illinois College of Medi-

cine.

The Occupational Disease Clinic

MILTON H. KRONENBERG, M.D., Chicago

Assistant Professor of Bacteriology and Public Health, University of

Illinois College of Medicine.

Room 17

MONDAY EVENING, 6:30

An informal dinner and round table discussion, intended primarily for state and county medical society committees on industrial health, will be held. The program will include:

Use of Visiting Nurses in Industry.

MISS JOANNA JOHNSON, R.N., Milwaukee

Chairman, Industrial Nursing Section, National Organization for Public Health Nursing

Progress in Official Agencies.

J. J. BLOOMFIELD, Bethesda, Md.

Chief, States' Relations Section, U. S. Public Health Service, National

Institute of Health.

Postgraduate Education in Industrial Health

WALTER L. BIERRING, M.D., Des Moines, Iowa.

Commissioner, State of Iowa Department of Health.

Crystal Room

TUESDAY MORNING, 9:30

Conservation of Manpower in Connecticut.

CLIFFORD KUH, M.D., New Haven, Conn.

Chairman, Committee on Industrial Health, Connecticut State Medical Society.

Health Education for Industrial Workers.

LEVERETT D. BRISTOL, M.D., New York.

Chairman, Committee on Education and Publications, Council on Industrial Health, American Medical Association.

Lecture on Traumatic Surgery

(Speaker to be announced)

Industrial Ophthalmology.

A Report by the Committee on Industrial Ophthalmology, Section on Ophthalmology, American Medical Association.

ALBERT C. SNELL, M.D., Chairman, Rochester, N. Y.

ARTHUR CULLER, M.D., Dayton, Ohio

HEDWIG S. KUHN, M.D., Hammond, Ind

Placement of the Worker in Industry

JOSEPH TIFFIN, Ph.D., Lafayette, Ind

Professor of Industrial Psychology, Purdue University.

Red Lacquer Room

TUESDAY AFTERNOON, 2:30

Conservation of Hearing in Industry.

C. C. BUNCH, Ph.D., Evanston, Ill.

Department of Speech Reeduction, School of Speech of Northwestern University.

Recent Trends in Physical Examinations Under Civil Service.

VERNE K. HARVEY, M.D., Washington, D. C.

Medical Director, U. S. Civil Service Commission.

Vitamin Administration in Industry.

A Report Prepared by Representatives of the Council on Foods and Nutrition and the Council on Industrial Health

J. S. McLESTER, M.D., Birmingham, Ala.

GEORGE R. COWGILL, Ph.D., New Haven, Conn

R. M. WILDER, M.D., Rochester, Minn.

LEVERETT D. BRISTOL, M.D., New York

LEROY U. GARDNER, M.D., Saranac Lake, N. Y.

CLARENCE D. SELBY, M.D., Detroit.

Medical Service Plans for Small Industry

MYER S. BLOOM, M.D., Binghamton, N. Y.

Red Lacquer Room

WEDNESDAY, JANUARY 14

Field trips have been arranged for a limited number of physicians interested in details of industrial medical department administration. Further details will be provided to registrants during the Congress.

Also on Wednesday, January 14, a clinical program will be held in conjunction with the University of Illinois College of Medicine, illustrating practical problems in industrial medicine, industrial hygiene and traumatic surgery.

CLINICAL PROGRAM

University of Illinois College of Medicine,
1853 West Polk Street, Room 423,
Chicago

WEDNESDAY MORNING, 9:30

Pulmonary Capacity Tests in Health and Disease.

Demonstration:

GEORGE E. WAKERLIN, M.D.

Professor of Physiology.

Difficulties and Fallacies of Interpretation of Chest X-Ray Films

Demonstration:

ADOLPH HARTUNG, M.D.

Professor of Radiology.

Practical Points on Patch Testing in Occupational Dermatitis

Demonstration:

LEONARD F. WEBER, M.D.

Associate Professor of Dermatology.

Urinary, Blood and Other Tests of Value in Cases of Industrial Toxicology

Demonstration:

WILLIAM D. McNALLY, M.D.

Coroner's Chemist, Cook County, Chicago

WEDNESDAY AFTERNOON, 2:00

Evaluating the Traumatic Abdomen.

CHARLES A. PLESTOW, M.D.

Associate Professor of Surgery.

Dental and Oral Manifestations of Occupational Origin.

ISAAC SCROUR, D.D.S., Ph.D.
Professor of Dental Histology,
and
BERNARD SARNAT, D.D.S., M.D.
College of Dentistry.

The Industrial Hernia—Is It a Cause for Rejection?

WILL F. LYON, M.D.
Associate Professor of Surgery.

The Occupational Anemias.

CARROLL BIRCH, M.D.
Assistant Professor of Medicine.

ADDRESSES BY THE PRESIDENT AND THE PRESIDENT-ELECT

Dr. Frank H. Lahey, President of the American Medical Association, has been scheduled to deliver the following addresses during December:

December 2.—Rochester Academy of Medicine, Rochester, N. Y.

December 4.—Harrisburg Academy of Medicine, Harrisburg, Pa.

Dr. Fred W. Rankin, President-Elect of the American Medical Association, has been scheduled to deliver the following addresses:

December 9.—Southern Surgical Association, Pinehurst, N. C.

December 15.—Fulton County Medical Society, Atlanta, Ga.

EXHIBITS FROM HEADQUARTERS

December 1-5.—Wells High School, Chicago (Health Week):

"Periodic Health Examination."
"Prevention of Accidents."

December 1-5.—Carl Schurz High School, Chicago (Health Week):

"Health Material."

December 3.—Woman's Hospital, Detroit (Annual Clinical Hospital Day):

"The Use and Abuse of Barbiturates."

December 4.—Detroit Institute of Technology, Detroit (Open House, College of Pharmacy and Department of Chemistry):

"The Use and Abuse of Barbiturates."

December 4.—Women's Auxiliary, Marion County Medical Society, Fairmont, W. Va. (Health Institute):

"Your Health."

December 11-14.—Health Exposition, Kansas City, Mo.:

"The Human Factory."
"Respiratory System in Health and Disease."
"Heart Disease."
"Syphilis."
"Cancer."
"Prevention of Burns."
"Dangers of Self Diagnosis and Self Medication."
"Mechanical Nostrums."
"The Public Health."

WOMAN'S AUXILIARY

New York

At a business meeting of the Fulton County auxiliary at the home of Mrs. J. Edward Grant of Northville, the card party held at the Adirondack Inn, Sacandaga, in July by the auxiliary for Bundles for Britain was reported to have netted \$114, which will be divided equally between the Gloversville and Johnstown branches of the organization. The auxiliary made it possible for one underprivileged child to spend one week at the Fulton County Children's Camp during the summer.

At the first fall meeting of the Herkimer County auxiliary held in Herkimer, the guest speaker was Mrs. Marcus DeWolfe, who spoke on India. Mrs. DeWolfe lived there several years. The members discussed the advisability of meeting every month. The by-laws were revised and it will meet every month, the alternate month to serve as a sewing bee for the British War Relief. The summer camp at Pine Crest Sanatorium is its pet activity. The auxiliary held a card party and raised \$70, with which a slide was purchased for the playground.

Mrs. George B. Adams, president of the state auxiliary, addressed the Onondaga County auxiliary on May 29, when Mrs. George Sincerbeaux, retiring president, presented the gavel to Mrs. Carlton Bullard; other officers for the year include: first vice president Mrs. J. D. Sands, second vice president Mrs. Jason L. Wiley, treasurer Mrs. Herbert Jones, secretary Mrs. A. B. Chidester. It was decided to send two girls to the Girl Scout Camp for two weeks.

Attended by more than two hundred people, a ball was held at the Elks Club in Hudson by the women's auxiliary of Columbia County for the benefit of Bundles for Britain. Mrs. Henry C. Galster, president of the Hudson branch, was the chairman. Guests were present from New York, New Rochelle, Amsterdam, Albany and most of the towns of the county. The amount realized was over \$200.

South Dakota

At a meeting of the board of the Woman's Auxiliary to the South Dakota State Medical Association in Sioux Falls, November 18, the national president of the Woman's Auxiliary to the American Medical Association, Mrs. R. E. Mosiman of Seattle, spoke on different phases of the auxiliary work; other guests of honor were Mrs. F. C. Nilsson, president of the South Dakota Auxiliary, Sioux Falls, and Mrs. Zelda Krueger, Red Cross executive secretary. The Seventh District Medical Auxiliary were hosts at a luncheon which was attended by thirty-five members from throughout the state.

Wisconsin

The Woman's Auxiliary to the Dane County Medical Society presented Dr. Paul C. Barton in a talk on "Beauty Aids and Adds" in Madison, May 12.

At Fond du Lac on May 22, the Woman's Auxiliary to the Fond du Lac County Medical Society voted to send eight girl scouts to camp in the summer. Reports of recent card parties showed that \$73.50 had been cleared for philanthropic projects. Mrs. W. C. Finn of Fond du Lac is the new president, chosen to succeed Mrs. A. M. Hutter.

Gardens in May occupied the attention of the Woman's Auxiliary to the Milwaukee County Medical Society.

Mr. Robert Boerner of the Milwaukee Park Commission addressed the May 9 meeting. Colored slides of the flowers in Milwaukee parks were shown.

Activities in April and May included a luncheon at Hart House, near Milwaukee, at which the president, Mrs. C. D. Partridge, entertained the officers and board of directors, and a luncheon at the Wisconsin Club, Milwaukee, given by the officers, directors and past presidents in honor of Mrs. Partridge.

At their annual open meeting in Appleton, May 5, twenty-two members of the Woman's Auxiliary to the Outagamie County Medical Society were hostesses to two hundred and fifty guests. The speaker, Dr. Amy Louise Hunter of Madison, chief of the bureau of maternal and child health for the state of Wisconsin, discussed infantile paralysis, premature babies, education for motherhood and prevention of tuberculosis.

The Rock County auxiliary met in Beloit, May 27, to hear Mrs. Wayne Munn of Janesville give a reading of "The American Way."

The Woman's Auxiliary to the Waukesha County Medical Society entertained fifty people at a presidents' tea at the home of Mrs. A. G. Nixon in Hartland, May 22. Presidents and other representatives of lay organizations were invited to hear Mr. George Larson, assistant secretary of the Wisconsin State Medical Society, speak on experiments in voluntary sickness insurance. The audience asked many questions of the speaker. The auxiliary voted \$10 to the Dousman Home and Farm School for Boys toward a fund to provide adequate isolation facilities for scarlet fever cases.

In May, Mrs. Gerald H. Friedman of Milwaukee, state Hygeia chairman, reported that Wisconsin had exceeded the 1940 quota; to date, subscriptions number 880, compared with last year's 875.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Physicians' Art and Garden Societies.—The Los Angeles Physicians Art Society opened the fall season with a dinner at the Los Angeles County Medical Association on November 28. Mr. Roger Noble Burnham, Los Angeles, modeled a portrait in relief of a member of the audience, and Mrs. Burnham discussed the history of sculpture. The Los Angeles County Medical Garden Club recently held its fall flower show. Officers of the garden club include Drs. Robert B. Hope, president; Hyman Miller and Albert G. Bower, vice presidents, and Samuel Ayres Jr., secretary.

New Comprehensive Study of the Common Cold.—The University of California Medical School, San Francisco, began a comprehensive two year study of the common cold and other respiratory diseases in November. Ten members of the staff of the university will carry on the research under the direction of Dr. William J. Kerr, professor of medicine. One phase will be a study of the physical influences caused by changes in the weather and overcooling. A special room has been built large enough for six persons, in which the temperature and humidity of the air can be changed to any climatic condition quickly and at will. An attempt will be made to correlate all the facts concerning conditions which make a person susceptible to a cold.

ILLINOIS

Plan to Release "Socially Safe" Mental Patients.—Dr. Alfred P. Bay, assistant managing officer of the Alton State Hospital, Alton, has been appointed assistant state alienist to direct the program under which state officials propose to release several thousand "socially safe" patients from state mental hospitals, newspapers reported recently. Dr. Bay will supervise an outpatient clinic plan under which patients released will report regularly to hospital physicians for examination. He will be responsible for the release of patients at the Alton, Anna, Peoria, Jacksonville and East Moline hospitals.

Society News.—Dr. George L. Drennan, Jacksonville, discussed "Deafness in Childhood" before the Madison County Medical Society in Collinsville, October 3.—Dr. George C. Turner, Chicago, discussed "Early Diagnosis of Pulmonary Tuberculosis" before the Madison County Medical Society in Edwardsville, November 7.—The Peoria Medical Society and the local dental society were addressed at a joint dinner meeting in Peoria, November 18, by Dr. Joseph E. Schaefer, Chicago, on "Repair of Facial Injuries." The medical society was addressed, November 4, by Dr. Franklin G. Ebaugh, Denver, on "New Factors Regarding Mental Disorders."

Chicago

The Ludvig Hektoen Lecture.—The eighteenth Ludvig Hektoen Lecture of the Frank Billings Foundation, Institute of Medicine of Chicago, will be delivered on January 23 at the Palmer House by Dr. Stanhope Bayne-Jones, professor of bacteriology, Yale University School of Medicine, New Haven, on the subject "Tetanus."

INDIANA

Crum Guilty of Gross Immorality in Use of Etherator.—The Supreme Court of Indiana on November 3 upheld the action of the board of medical registration and education in revoking three licenses held by Heil E. Crum, one authorizing him to practice naturopathy, another to practice chiropractic and a third to practice electrotherapy, on the ground that the licensee was guilty of "immoral conduct." The evidence disclosed that, after attending high school, Crum entered the College of Drugless Physicians in Indianapolis, from which he was graduated at the end of one year with the degrees of doctor of naturopathy, doctor of electrotherapeutics, doctor of chiropractic and doctor of herbal materia medica. "The evidence supports the inference," said the Supreme Court, "that this institution was nothing more than a 'diploma mill.'" Crum received his three licenses, without examination, by virtue of a clause in the 1927 medical practice act of Indiana, commonly referred to as a "grandfather" clause, under which licenses

were issued to persons already practicing any system or method of healing taught by the school or college of which the applicant was a graduate. The gist of the complaint against Crum was that he employed a mechanical contrivance called an "etherator" or "coetherator" which was totally devoid of any therapeutic value. As described by the Supreme Court, the etherator was a small wooden box with a number of holes in the front over which various colors of thin paper were pasted. On the inside was an ordinary light bulb with a cord for making contact with electricity. The bulb could be moved about so that the light would penetrate the various paper covered holes. The box contained a quantity of disconnected wire such as is commonly used for radio aeriels and a glass tube filled with ordinary hydrant water. There was a pedal and a dial on the outside of the box, neither of which had any connection with the interior. The method used in treating human ailments was to have the patient moisten a slip of paper with saliva and deposit it through a slot on the top of the box, although it was claimed that the same results could be obtained by similar use of the patient's photograph or a specimen of his handwriting. After this was done, Crum would rub the pedal with his thumb and talk to the machine, repeating the popular names of diseases and organs of the body. Many of the diseases which he claimed to be able to treat and relieve, and in some instances cure, were cancer, blindness, arthritis, nervous disorders, hemorrhoids, abscesses, kidney ailments, stomach disorders, leakage of the heart, skin ailments, ovarian trouble, varicose veins and tumors. Crum further claimed that he could lengthen or shorten a patient's legs, cause amputated fingers to grow back into place and fill cavities in teeth, not with a foreign substance but by restoring them to their original condition. He said that it was not necessary for patients to be present or visit his office but that he could broadcast treatments to them wherever they might be located. By use of the machine, he claimed, he could fertilize fields to a distance of 70 miles, could kill dandelions over any particular area, could treat golf greens and could give financial treatments by means of which money could be put into the hands of his patients. The mere mention of the extravagant claims made by Crum, the court thought, was sufficient to suggest their untruthfulness and brand them as designedly fraudulent. Crum contended that by virtue of the three licenses that had been issued to him the state had authorized him to engage in the activities that prompted the revocation proceeding. In answer to this contention the Supreme Court considered it unnecessary to undertake to define the practice of chiropractic, naturopathy or electrotherapy. To the court it was enough to say that it could not be judicially presumed that the legislature intended to authorize a course of conduct so reprehensible and revolting as to shock the sensibilities of reasonable men.

IOWA

Postgraduate Lectures.—The speakers' bureau of the Iowa State Medical Society sponsored the following postgraduate lectures during November:

- Dr. Kellogg Speed, Chicago, A Discussion of War Wounds, Davenport, November 4.
- Dr. Jerome R. Head, Chicago, Chest Injuries, Marshalltown, November 4.
- Dr. Willis M. Fowler, Iowa City, Diseases of the Blood, Newton, November 4.
- Dr. Paul C. Bucy, Chicago, Making a Neurologic Examination in General Practice, Ottumwa, November 4.
- Dr. Horace M. Korns, Iowa City, Diagnosis and Treatment of Pneumonia, Newton, November 11.
- Dr. John W. G. Caldwell, Des Moines, Recent Treatment of Pneumonia, Toledo, November 13.
- Dr. Harold F. Buchstein, Minneapolis, Making a Neurological Examination, Jefferson, November 13.
- Dr. Arthur U. Desjardins, Rochester, Minn., Therapeutic Value of X-Ray, Boone, November 13.
- Dr. Wilbur C. Thatcher, Fort Dodge, Management of Obstetric Difficulties, Spirit Lake, November 18.
- Dr. Walter A. W. Kirch, Des Moines, Common Diseases of the Ear, Nose and Throat, Ottumwa, November 18.
- Dr. Frank R. Peterson, Iowa City, Acute Surgical Conditions in the Abdomen in Childhood, Newton, November 18.
- Dr. Daniel J. Glomset, Des Moines, Treatment of Heart Failure, Red Oak, November 18.
- Dr. Frederic W. Schlutz, Chicago, Common Disease of Childhood, Carroll, November 20.
- Dr. Dean M. Lierle, Iowa City, Diagnosis and Treatment of Common Conditions of the Ear, Nose and Throat, Newton, November 25.

KANSAS

Dr. Westman Named Federal Consultant in Epidemiology.—Dr. Ragnar T. Westman resigned as health director of Kansas City November 1 to assume rank as surgeon of the U. S. Public Health Service and serve as federal consultant in epidemiology to extra cantonment and defense areas, it is reported. He is stationed in Bethesda, Md.

Society News.—The Sedgwick County Medical Society designated its November 18 meeting as "University of Kansas School of Medicine Night"; the speakers were Drs. Harry R. Wahl, dean of the school, on activities of the school; John A. Billingsley, Kansas City, "Aniseikonia"; Mahlon H. Delp, Kansas City, "Treatment of Arsenical Dermatitis with Vitamin C" and Frank C. Neff, Kansas City, Mo., "Adrenal Androgenic Tumors."

Cooperating Committees on Legal Medicine.—The Kansas Medical Society and the Kansas Bar Association have appointed committees on legal medicine to study jointly and prepare recommendations on matters of interest to both the legal and the medical profession. Members of the bar association committee are Mr. Claude I. Depew, Wichita, chairman; Mr. Roy C. Davis, Hutchinson; Mr. John H. Hunt, Topeka; Mr. Oscar P. May, Atchinson; Mr. Larue Royce, Salina, and Mr. Thomas M. Van Cleave, Kansas City. Members of the medical society's committee are Drs. Earl L. Mills, Wichita; Clyde D. Blake, Hays; Eugene J. Bribach, Atchinson; John J. Brownlee, Hutchinson; John L. Lattimore, Topeka, and Laurence S. Nelson, Salina.

MICHIGAN

Personal.—Dr. Charles H. P. G. Benning, Royal Oak, deputy commissioner of health of Oakland County for more than thirteen years, has been assigned to the department of health of Puerto Rico, San Juan, as venereal disease consultant by the U. S. Public Health Service.—Dr. Thomas P. Crane, Dearborn, has been placed in charge of the outpatient department at the Veterans' Administration Facility in Dearborn, succeeding Dr. Edward O. Sage, who was transferred to New Orleans.—Citizens of Baraga sponsored a dinner recently in honor of the seventy-fifth birthday of Dr. Romulus S. Buckland who has been practicing in Baraga for forty-one years. He was presented with a plaque bearing a replica of himself mounted on horseback.

Society News.—Dr. Lyman T. Rawles, Fort Wayne, Ind., is the new president of the Northern Tri-State Medical Association. Other officers of the association, which met in annual session in Detroit recently, include Drs. E. Benjamin Gillette, Toledo, vice president; Douglas Donald, Detroit, treasurer, and Floyd R. N. Carter, South Bend, secretary. The sixty-ninth annual meeting of the association will be held in Fort Wayne, April 7, 1942.—Dr. Ernest E. Irons, Chicago, addressed the medical section of the Wayne County Medical Society, Detroit, November 10, on "Aspiration Pneumonia." Dr. Michael L. Mason, Chicago, discussed "Significant Factors in the Development of Infections of the Hand" before the surgical section of the society, October 27.—Dr. Herman H. Riecker, Ann Arbor, addressed the Calhoun County Medical Society, Battle Creek, October 7, on "Classification and Management of Hypertension."

NEBRASKA

Hospitals Cooperate in Clinic.—The staffs of the Lincoln General and Bryan Memorial hospitals, Lincoln, sponsored a two day clinic, October 17-18, with sessions at both hospitals. Included among the guest speakers were Drs. Fred J. Hodges, professor of roentgenology and chairman of the department, Stanley M. Goldhammer, assistant professor of internal medicine, University of Michigan Medical School, Ann Arbor, Philip M. Northrop, D.D.S., assistant professor of oral surgery, University of Michigan School of Dentistry, Ann Arbor, and Dr. Robert Lee Hoffmann, Kansas City, Mo.

NEW JERSEY

Society News.—Dr. Thomas Fitz-Hugh Jr., Philadelphia, discussed "Management of Anemia in General Practice" before the Camden County Medical Society in Camden, November 4.—The Hudson County Medical Society was addressed in Jersey City, October 7, by Dr. James William Hinton, New York, on thyroid disease.

New State Director of Health and Physical Education.—Dr. Wilson G. Guthrie, Newark, has been appointed director of health and physical education of the state department of public instruction to succeed the late Dr. Allen G. Ireland, Trenton. Dr. Guthrie graduated at the University of Tennessee College of Medicine, Memphis, in 1918.

NEW YORK

Appointments to Industrial Council.—Dr. Benjamin M. Eis, Brooklyn, has been appointed a member of the state industrial council to fill a vacancy caused by the death of Dr. Henry Joachim, Brooklyn, and Dr. Van S. Laughlin, Westfield, has been named to fill a vacancy that occurred with the resignation of Dr. William D. Johnson, Batavia.

Annual Surgical Session at Buffalo.—The annual meeting and clinical day of the Western New York Surgical Society was held at the Edward J. Meyer Memorial Hospital, Buffalo, November 27, with Drs. John D. Stewart, Buffalo, and Edward D. Churchill, John Homans professor of surgery, Harvard Medical School, Boston, as guest speakers. Others on the program included:

Dr. Henry N. Kenwell, Buffalo, Liver Abscess with the Report of the Surgical Treatment of a Recent Case.
Dr. Donald P. Ross, Niagara Falls, Gastric Resection for Peptic Ulcer.
Dr. George W. Cottis, Jamestown, Perpetuation of the Fallacy of Peritoneal Drainage.
Dr. Joseph D'Errico Jr., North Tonawanda, Surgery of Renal Anomalies.
Dr. James P. Cole, Buffalo, Importance of the Lumbosacral Joint in Low Back Pain.
Dr. Leon J. Leahy, Buffalo, Surgical Collapse Therapy in Pulmonary Tuberculosis.

New York City

Professor Appointed.—Dr. William Carson Von Glahn, formerly associate professor of pathology at Columbia University College of Physicians and Surgeons, has been appointed professor of pathology at New York University College of Medicine and director of the department of pathology and laboratories at Bellevue Hospital. An agreement worked out between the city and New York University gives the university the privilege of nominating all members of the department of pathology of Bellevue Hospital and of the laboratory staff, it is reported.

Conference on Tuberculosis.—The Tuberculosis Sanatorium Conference of Metropolitan New York will sponsor a meeting on chronic pulmonary diseases at Cornell University Medical College December 10. Dr. Max Pinner, chief of the division of pulmonary diseases, Montefiore Hospital for Chronic Diseases, will read a paper on "Experimental Studies on Bronchiectasis and Atelectasis," which was prepared by Dr. Pinner and Dr. Joseph Tannenber, Batavia. Dr. John E. Leach, clinical assistant in medicine, Memorial Hospital for the Treatment of Cancer and Allied Diseases, will present a paper on "Radiation Pleuropulmonitis."

Survey of Abortion Racket.—A comprehensive survey of a citywide abortion racket was handed up in presentment form in Brooklyn Supreme Court, October 15, according to the New York Times. The grand jurors recommended a campaign of public education against the dangers of abortions and a penal code provision making it a misdemeanor to offer to perform a criminal abortion or to refer a patient to another physician for an illegal operation. The report also recommended increased vigilance by local police in detecting and reporting establishments for abortions and an interchange of information between the department of education and the police department. The replacement of the present medical grievance committee of ten members serving part time without compensation by a full time committee of physicians with compensation was also urged.

Lectures on Occupational Diseases.—The Medical Society of the County of Kings and Academy of Medicine of Brooklyn opened a course of lectures on industrial health and occupational diseases in Brooklyn, November 24. "Origins and Growth in Industrial Health" was discussed in the first series by Dr. Alfred E. Shipley, Brooklyn, Eugene B. Patton, director, division of statistics, New York State Department of Labor, and a speaker whose name was not announced. Other lectures include:

Drs. Samuel J. Kopetzky, New York, Albert F. R. Andresen, Brooklyn, Alec N. Thomson, Brooklyn, and Charles F. McCarty, Brooklyn, Role of the County Medical Society in an Industrial Health Program and the National Defense Program, December 1.
Mr. Henry D. Sayer, Drs. David J. Kaliski, New York, and Fred L. Moore, Brooklyn, Compensation Law: Progress and Present Interpretation, December 8.
Drs. John Hamilton Crawford, Brooklyn, and George G. Ornstein, New York, Relationship Between Injury and Disease, December 15.
Drs. Louis Berger, Joseph B. L'Episcopo, Samuel Potter Bartley and William E. Howes, Brooklyn, Traumatic and Orthopedic Surgery, January 5.
Drs. John E. Jennings, Joseph E. Golding and Edwin K. Morgan, Brooklyn, Traumatic Surgery, January 12.

Various aspects of occupational diseases will be discussed by Drs. Leonard Greenburg and May R. Mayers, New York, January 19; Abraham Walzer, Brooklyn, Max Harten, Brooklyn, and Eugene R. Marzullo, Brooklyn, January 26; Irving Gray, Brooklyn, and George N. Edson, Flushing, N. Y., Feb-

ruary 2; Charles T. Graham-Rogers, Brooklyn, John J. Wittmer, Brooklyn, Niel E. Eckelberry, New York, and a speaker to be announced, February 9, and Harry Heimann, Thomas A. Gonzales, New York, and Edmund A. Whalen, LL.B., counsel, Medical Society of the County of Kings, February 16.

OHIO

Youth Health Program Resumed on Smaller Scale.—The NYA health program in Ohio will be resumed on a smaller scale through adjustments made by local officials, the state medical journal reports. A reduction in the allocation of funds to the project was responsible for a recent curtailment of the program. Under the new set up a reduction will be made in the number of areas of the NYA in Ohio from eight to six. A health supervisor will be provided for each of the six districts with Dr. Carl A. Wilzbach, health commissioner of Cincinnati, continuing as state health consultant. Use will be made in a limited way of the physicians who had been engaged in the various counties on a per diem basis to make physical examinations of NYA youths. For the present those who will be given examinations fall into three classifications: those scheduled to go to camps and resident centers, those with obvious physical defects and those receiving shop training for subsequent employment in national defense industries.

Personal.—Dr. William E. Lower, for many years chief of staff at the Lutheran Hospital, Cleveland, was honored at a luncheon on October 16 by friends and associates of the hospital. The luncheon was planned by Dr. Norman C. Yarian, the present chief of staff, who succeeded Dr. Paul H. Krebs, a former chief of staff, he having succeeded Dr. Lower and Dr. Emanuel Klaus, who is on the staff.—Dr. Bruno Gebhard, director of the Cleveland Museum of Health and Hygiene, has been invited by Dr. Angel de la Garza Brito, dean of the School of Public Health and Hygiene, Mexico, to visit Mexico City to confer with local authorities on the establishment of a health museum.—Dr. James F. Wilson, Washington C. H., secretary of the Fayette County Medical Society, recently completed his fifteenth year as health commissioner of the county.—Dr. James W. Fitch has retired as physician for the Home for Aged Women, Portsmouth, a service which he had donated for forty years.—Charles L. Spoler has been named executive secretary of the Scioto County Tuberculosis and Health Association. He had been formerly connected with the WPA administrative staff at Zanesville.

OREGON

Diseases of the Chest.—The second annual postgraduate session of diseases of the chest will be held at the University of Oregon Medical School, Portland, December 11-13, under the auspices of the Pacific Northwest Section of the American College of Chest Physicians and the medical school. The program has been designed as a review of present day therapy in diseases of the chest. The guest speaker will be Dr. Leo Eloesser, clinical professor of surgery, Stanford University School of Medicine, San Francisco. His subjects will be "Causes of Pulmonary Cavitation" and "Treatment of Pulmonary Cavities by Various Methods of Closed Drainage."

PENNSYLVANIA

Society News.—The Reading Eye, Ear, Nose and Throat Society was recently organized with Dr. James E. Landis as president and Dr. Paul C. Craig, secretary. Official recognition and approval was given to the new society by the American Academy of Ophthalmology and Otolaryngology at its meeting in Chicago in October. Membership will be extended by invitation to eligible physicians who hold active membership in the Berks County Medical Society and the Medical Society of the State of Pennsylvania.

Philadelphia

Annual de Schweinitz Lecture.—Dr. Harry Friedenwald, professor emeritus of ophthalmology, University of Maryland School of Medicine, Baltimore, delivered the fourth annual de Schweinitz Lecture before the Section on Ophthalmology of the College of Physicians of Philadelphia, November 19, on "The Paths of Progress of Ophthalmology."

Meeting on Medical History.—The section on medical history of the College of Physicians of Philadelphia presented the following program, November 10: Drs. Pascal F. Lucchesi, "History of Poliomyelitis"; Eugene P. Campbell, "Influenza—Past and Present," and Milton I. Rose, "Contributions of Pediatrics to Modern Public Health Philosophy."

WEST VIRGINIA

Society News.—Dr. Richard B. Cattell, Boston, addressed the Ohio County Medical Society, Wheeling, September 26, on "Diagnosis and Management of Biliary Tract Disease." Dr. Joseph H. Barach, Pittsburgh, addressed the society, October 10, on "Present Day Treatment of Diabetes and Complications."—Dr. Martin L. Bonar, Charleston, addressed the Fayette County Medical Society, Montgomery, recently on diseases of the skin.—Dr. Dean B. Cole, Richmond, Va., addressed the Cabell County Medical Society, Huntington, September 11, on "Pneumothorax Treatment of Tuberculosis." Dr. Warren T. Vaughan, Richmond, Va., addressed the society recently on "Problems in Allergy of Interest to the General Practitioner."—Dr. George P. Sturgis, Boston, addressed the Kanawha Medical Society, Charleston, recently on "Heart Disease in Pregnancy."

PUERTO RICO

Lectures on Tropical Medicine.—The School of Tropical Medicine of the University of Puerto Rico, San Juan, under the auspices of Columbia University, opened a series of lectures on tropical medicine, November 5, to continue until January 21. The lecturers are Dr. Ramón M. Suárez, head of the department of clinical medicine of the school; Dr. Rafael Rodríguez Molina, assistant professor of clinical medicine, and Dr. Federico Hernández Morales, medical supervisor of the University Hospital, San Juan. The subjects covered are lymphogranuloma venereum; sprue, pellagra, ariboflavinosis and other deficiency diseases; Weil's disease; yaws, rat-bite fever; typhoid; paratyphoid A and B; amebic dysentery; tropical lymphangitis; clinical aspects of intestinal parasites; malarial fevers and blackwater fever; Schistosomiasis mansoni. Science reports that the following have been appointed visiting professors at the School of Tropical Medicine:

Col. Alexander T. Cooper, M. C., U. S. Army, retired, San Juan, military medicine.

Dr. Joseph O. Dean, San Juan, U. S. Public Health Service, public health practice.

David B. Dill, Ph.D., professor of industrial physiology and consulting physiologist to the hygiene department, Harvard University, Cambridge, physiology.

Dr. James A. Doull, professor of hygiene and public health, Western Reserve University School of Medicine, Cleveland, epidemiology.

Dr. Thomas H. D. Griffiths, San Juan, U. S. Public Health Service, public health.

Dr. William B. Porter, professor of medicine, Medical College of Virginia, Richmond, medicine.

William H. Tallaferro, Ph.D., dean, Division of the Biological Sciences, University of Chicago, protozoology.

GENERAL

New Radio Health Campaign.—The Federal Security Agency, the U. S. Public Health Service and the U. S. Department of Agriculture are cooperating with the Women's National Emergency Committee and the National Broadcasting Company in presenting the new fall and winter series of "Listen America," the coast to coast radio campaign for better national health, which opened on November 23. Included on the premier program was Dr. William Henry Sebrell Jr., of the Federal Security Agency, Washington, D. C.

Dr. Williams Receives Vitamin Award.—Robert R. Williams, D.Sc., chemical director of the Bell Telephone Laboratories, New York, since 1925, was presented with the annual award of the Associated Grocery Manufacturers of America, Inc., during the session in New York, November 7, in recognition of his work on the vitamins. Dr. Williams is credited with isolating Vitamin B₁. In 1938 the Chicago Section of the American Chemical Society presented the Willard Gibbs medal to Dr. Williams for "outstanding work in connection with the study and isolation of the beriberi vitamin."

Examinations for Orthoptic Technicians.—The American Orthoptic Council will conduct two examinations for orthoptic technicians in 1942. The first examination will be held in New York preceding the annual session of the American Medical Association in Atlantic City in June, and the second will be held in San Francisco preceding the meeting of the American Academy of Ophthalmology and Otolaryngology in October. One written examination will be conducted throughout the country in May, one month prior to the first examination. Applications to take this examination must be received before April 1. Only those passing the written examination will be eligible to take either of the practical and oral examinations.

Bailey K. Ashford Award.—The American Society of Tropical Medicine at its annual meeting in St. Louis, November 11, presented the Bailey K. Ashford Award in Tropical Medicine to Lloyd E. Rozeboom, Sc.D., associate in medical entomology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, for proving malaria transmission in

a variety of mosquito suspected but never demonstrated to be a carrier of the disease. The award of \$1,000, a bronze medal and travel expenses has been made available by Eli Lilly & Co., Indianapolis. A native of Orange City, Iowa, Dr. Rozeboom is 33 years of age. He served as assistant medical entomologist at the school of hygiene and public health from 1931 until 1934 and in this year received his D.Sc. degree at Johns Hopkins University. He has been medical entomologist at the Gorgas Memorial Laboratory, Ancon, C. Z., since 1934.

Applications for Cancer Fellowships.—The Finney-Howell Research Foundation, Inc., announces that all applications for fellowships for next year must be filed in the office of the foundation, 1211 Cathedral Street, Baltimore, by Jan. 1, 1942. Applications received after that date cannot be considered for 1942 awards, which will be made the first of March 1942. Fellowships carrying an annual stipend of \$2,000 are awarded for the period of one year, with the possibility of renewal up to three years; when deemed wise by the board of directors of the foundation, special grants of limited sums may be made to support the work carried on under a fellowship. The foundation was provided for in the will of the late Dr. George Walker of Baltimore to support "research work into the cause or causes and the treatment of cancer." The will directed that the surplus income from the assets of the foundation together with the principal sum should be expended within ten years to support a number of fellowships in cancer research.

Special Society Elections.—Dr. Noel Paul Hudson, Columbus, Ohio, was chosen president-elect of the American Society of Tropical Medicine at its meeting in St. Louis conjointly with the Southern Medical Association, November 10-13, and Ernest Carroll Faust, Ph.D., New Orleans, was inducted into the presidency. Other officers include Drs. Joseph S. D'Antoni, New Orleans, vice president, and E. Harold Hinman, Wilson Dam, Ala., secretary-treasurer. Karl F. Meyer, Ph.D., of the George Williams Hooper Foundation for Medical Research, San Francisco, delivered the sixth Charles Franklin Craig Lecture on Tropical Medicine on "The Known and the Unknown in Plague." At the annual luncheon of the society Dr. Thomas T. Mackie, New York, the outgoing president, delivered his address on "Observations on the Early History of Tropical Medicine."—Dr. C. Sidney Burwell, Boston, was named president of the American Clinical and Climatological Association at its annual meeting in Boston, October 27. Other officers chosen include Drs. C. Maurice Pincoffs, Baltimore, and Francis M. Rackemann, Boston, vice presidents, and James Bordley III, Baltimore, secretary. The next annual session will be held in Princeton, N. J., Oct. 12-14, 1942.

Pharmacopoeia Convention.—The board of trustees of the United States Pharmacopoeial Convention announces that the adjourned meeting of the U. S. P. convention will reconvene at the Statler Hotel, Cleveland, on April 7. This meeting is in accordance with instructions given by the 1940 convention "... to meet at the call of the Board of Trustees to receive the report of the Committee on Constitution and By-Laws ..." This committee consists of nine voting members of physicians, pharmacists and one representative of a governmental agency:

Dr. Allen H. Buncie, Atlanta, Ga., chairman.
Wortley F. Rudd, Ph.D., Richmond, Va.
Patrick H. Costello, Cooperstown, N. D.
Carson P. Frailey, Washington, D. C.
Dr. William A. Groat, Syracuse, N. Y.
Dr. Theodore G. Klumpp, Chicago.
Charles H. Rogers, D.Sc., Minneapolis.
Dr. Torald H. Sollmann, Cleveland.
Dr. Horatio C. Wood Jr., Philadelphia.

Ex officio members are Dr. Cary Eggleston, New York, Lewis E. Warren, M.Sc., Washington, D. C., president and secretary of the convention, respectively, and E. Fullerton Cook, Ph.D., Philadelphia, chairman of the revision committee.

Dr. DeKleine Retires as Head of Red Cross.—The retirement of Dr. William DeKleine, Washington, D. C., as director of medical and health service of the American Red Cross was recently announced. His successor is Dr. Albert S. McCown, Washington, D. C., who has been serving as assistant director since June. Dr. DeKleine's service with the American Red Cross began in 1927 during the Mississippi Valley flood relief work. Since 1928, when he joined the regular staff, he has served as medical director. Previously he had been with the Michigan State Department of Health as director of the tuberculosis division. In 1925 he directed the five year child health demonstration at Mansfield, Ohio, with funds furnished by the Red Cross. He later supervised similar demonstrations at Fargo, N. D., and Salem, Ore. He graduated at Northwestern University Medical School, Chicago, in 1906. Dr. McCown was born in Lexington, Va., in 1890 and graduated at Johns Hopkins University School of Medi-

cine, Baltimore, in 1918. Positions he has held during his career include director of child health division, Washington State Health Department, 1934-1935; director of the division of maternal and child health, U. S. Children's Bureau, Washington, D. C., 1935-1937; deputy commissioner of health of the Michigan State Department of Health, Lansing, 1939, and director of the research and training unit, bureau of child hygiene, New York City Department of Health, 1940-1941.

Annual Meeting of Foundation for Infantile Paralysis.—The second annual medical session of the National Foundation for Infantile Paralysis was held at the New York Academy of Medicine, New York, December 3-5, with President Basil O'Connor, LL.B., presiding. A meeting of all medical advisers of the foundation, which opened the session, was followed by a program covering the activities of the committees of the foundation. At the second day's session a new feature was the presentation of prepared summaries of progress reports by the chairmen of the committees on education, nutritional research, virus research, medical publications, after-effects and epidemics and public health, participated in by grantees of the foundation. The afternoon was devoted to reports showing various means by which the foundation is combating the disease both from epidemiologic as well as from nursing and general public health points of view. The speakers were:

Dr. Felix J. Underwood, Jackson, Miss., Assistance Rendered by the National Foundation to States During Epidemic Periods.

Dr. Edward A. Piszcsek, Chicago, Study of an Outbreak in West Suburban Cook County.

Jessie L. Stevenson, R.N., consultant in orthopedic nursing, National Organization for Public Health Nursing, New York, Nursing Responsibilities in Epidemics of Infantile Paralysis.

Miss Lilyan Starr, executive secretary, Georgia state chapter, Atlanta, Functions of a State Chapter of the National Foundation During Epidemic and Endemic Poliomyelitis.

The president's dinner was held in the evening with Mr. O'Connor as the speaker. Committee meetings occupied the third day's program.

LATIN AMERICA

Pediatric Scholarship.—Dr. Julio Meneghello Rivera, assistant in the department of pediatrics of the Hospital Manuel Arriarán, will study at the Johns Hopkins University School of Medicine, Baltimore, under a scholarship from the American Academy of Pediatrics. The scholarship was awarded through the Sociedad Chilena de Pediatría to the author of the paper considered best in a competitive group.

Brazilian Ophthalmologists Form Examining Board.—The Brazilian Board of Ophthalmology was recently established with Dr. Cesario de Andrade, Rio de Janeiro, as president and Dr. Moacyr E. Alvaro, São Paulo, as secretary. The board is made up of the professors and assistant professors of ophthalmology of all the Brazilian universities and the presidents of all Brazilian societies of ophthalmology.

Medical Education in Mexico.—The theme for the annual contest sponsored by the Academia Nacional de Medicina de Mexico is this year "Medical Education in Mexico." The contest was to close on November 30. Two channels were open for consideration: "Suggestions on Modifications Proper for the Country" and "Pharmacodynamics of Sulfanilamide and Its Derivatives." The winner of the contest will be given 100 Mexican pesos and a certificate of honor and, in addition, a number of reprints of the winning essay.

Society News.—Members of the Sociedad de Oftalmología de Litoral were guests of the Sociedad de Oftalmología de Córdoba at a recent meeting with the following speakers: Drs. Carlos Weskamp, professor of ophthalmology in the faculties of medicine of Rosario and the National University of Litoral, Argentina, on "Observations on Serous Chorioretinitis of the Macula"; Juan M. Vila Ortiz, assistant professor of ophthalmology and ophthalmologist of the department of labor of Rosario Province, Argentina, "Considerations of Medical-legal Expert Testimony," and Isaac Cotlier, substitute professor of ophthalmology of the Faculty of Medicine of the National University of Litoral, Argentina, "The Stenopaeic Macular Perforations in Examinations for Refraction."

CORRECTION

Stipulations.—In the Bureau of Investigation department of THE JOURNAL for November 15, page 1727, appeared an abstract stating that the Federal Trade Commission had announced a stipulation with one Abram R. Canter of Pittsburgh, who sold "certain corsets and girdles known by the trade name 'Camp' and other so-called 'reducing girdles'" (quoted from the stipulation). This dealer is no part of the S. H. Camp & Company, and the latter firm reports that it markets no garment under the name Camp "reducing girdle."

Oct. 18, 1941.

International Conference of Scientists

The opening of a conference of scientists in London called by the British Association for the Advancement of Science has been described in a previous letter. The principles adopted by the council were announced. Intellectual freedom is held to be an essential condition of human progress. The special responsibility of scientists in the struggle to maintain intellectual liberty is asserted. The war now devastating the world involves an age old conflict of ideas. Liberal minds of the last generation were convinced that the battle for freedom of thought was finally won; yet once again this conviction is being violently assailed.

A recorded speech from General Smuts, a past president of the association, was broadcast from Capetown. He said that science was the greatest torch which the spirit of man had kindled in the modern world and that nothing—not even in this dark hour—should be allowed to interrupt its kindly light. It was fitting that this conference should be held in Britain, the mother of modern democracy. Science and democracy stood or fell together. The whole ethical basis of our western way of life was challenged. The "new order" was a return to the old slavery with the Gestapo added. In particular the proud position of science was challenged and degraded until it became no better than propaganda for myths and beliefs long discarded.

MAN IN DANGER OF EXTINCTION

Mr. H. G. Wells, who presided over a section on Science and the World Mind, said that what he would call the world mind was not really a coordinated mind at all: it was a gabble of unheeded and inconsecutive shoutings. If some vast superhuman intelligence was to ask "What is Man thinking now?" the answer would be "He is in fever and is delirious. He has muttered all sorts of things in the past, but now he is waking up very painfully and he talks louder." Unless man adapted himself to changing circumstances he might become extinct. Could he do this with sufficient rapidity to become a progressive superhomo or would he become one of a series of degenerating subhuman species or so fail as to end altogether? The records of the past were against the idea of any survival whatever of the human strain. We intellectual workers have to decide whether we are to be slaves and do what we are told by our masters the gangsters and profiteers or take our rightful place as servant masters of the world. We have the makings of a great international for pulling our scatterbrained world into a sane mentality. To have peace on the earth henceforth there must be federal control of international transport and a fundamental declaration of human rights, ensuring for all a fair participation in the resources of our planet. We needed a common language and a world encyclopedia.

Prof. Julius Lowy, formerly of Prague University, said that the health services of the European countries would not be equal to the great demands which would be made on them after the war. He proposed that the natural resources of Europe, such as sunlight, sea and mountain air, climatic factors and medicinal springs, should be used more systematically. A body should be appointed to draw up a scheme for their international use and to consider financial schemes for putting this into practice.

Mr. Allen of the American Red Cross spoke of the help his organization had given to France since the German occupation. They found the hospitals completely denuded. The

Germans had taken all the equipment and supplies. The French were left to set up hospitals in churches and schools and for their operating rooms used instruments from hardware stores.

Germany Violates International Convention for Repatriation of Sick and Wounded Soldiers

The conditions governing repatriation of sick and wounded prisoners of war are clearly stated in article 68 of the International Convention, to which Germany is a signatory. It runs as follows: "Belligerents shall be required to send back to their own country without regard to rank or numbers, after rendering them in a fit condition for transport, prisoners of war who are seriously ill or seriously wounded." Germany has now added a violation of this undertaking to the violations of treaties perpetrated by her in pursuit of her objects. Proposals for repatriation have been under discussion through the protecting power for many months, but the two governments were unable to reach agreement on the question of route and mode of transport. But on September 1 the British government received a proposal from the German government, through the Swiss legation, suggesting that sick and wounded should be repatriated in a British hospital ship through channel ports. This suggestion had been made by the British government several months before and rejected by Germany. The British government now accepted the proposal. On September 9 it received through the American embassy a message from the German government stating that there were twelve hundred British prisoners of war approved for repatriation by the mixed medical commission in Germany. The German government expressed the hope that sick and over age civil internees might also be repatriated. It also said that as we were sending only one hundred and fifty German prisoners of war our government might consider its gain in the exchange and send some civilians; also that we might fill available space in the hospital ships with German civilian women and children and men not of military age. Our government agreed to this and offered to send as a token of its intention a first batch of sixty German civilians. Then on October 2 the German government replied that "in view of the unsatisfactory attitude" of our government it would agree only to a limited exchange on a numerical basis. It was evident that it was attempting at the last moment to overthrow the previously agreed basis for repatriation. In view of this flagrant breach of faith our government reluctantly canceled the sailing of the ships. If it accepted the German change, the bulk of the British wounded would have lost their chance of repatriation. This breach of faith violates the International Convention, which states that repatriation shall take place "without regard to rank or numbers."

American Gift of Surgical Instruments

A gift of surgical instruments from the Columbia Medical Center of New York to the Charing Cross Hospital, London, was handed over by Sir Alfred Webb-Johnson, president of the Royal College of Surgeons. Mr. Lennox Ross Broster, a surgeon of the hospital, visited the United States this year to deliver two of the American society's official lectures. In making the presentation the president said that Mr. Broster's mission had been an enormous success. In addition to upholding the honor of British surgery he had made our American friends realize our gratitude and need. As a result, the Charing Cross Hospital had received this splendid gift of instruments, which came at a most opportune time, when the hospital was opening a new operating room. Mr. Philip Inman, chairman of the hospital, expressed the gratitude to the governors of the Columbia Medical Center.

SWITZERLAND

(From Our Regular Correspondent)

Oct. 15, 1941.

Investigation of Causes of Goiter

The question of the causes of goiter was discussed by Prof. Dr. J. U. Duerst before the Swiss goiter commission on the basis of a recent book, which summarizes investigations that cover a period of thirty-two years. These studies were begun at the suggestion of the late surgeon Professor de Quervain, who had studied the thyroid throughout his life. The initial investigations concerned the first appearance of the thyroid gland in fishes. The anatomists had disputed for decades whether the thyroid belongs to the respiratory or the digestive system. Duerst demonstrated that the thyroid, like the lung and the thymus, is an organ of the branchial canal, which is formed from remnants of the branchial clefts and thus must belong to the respiratory system. He was able to demonstrate in forty-five species of fish and in more than two hundred individuals that the thyroid and the thymus are closely connected with the gas exchange in the water. Great differences exist between the fish that live in the well oxygenated upper layers of water and the fish that inhabit the deeper strata in which the water has a lower oxygen and a higher carbon dioxide content. In surface fish the thyroid and thymus disappear after puberty, whereas in deep water fish the thyroid persists often into an advanced age and the thymus often shows proliferation at the time of puberty and is transformed into a reservoir for lymphocytes. That the thyroid as well as the thymus belongs to the gas exchange system has been corroborated in reptiles and in birds by the fact that the thyroid is attached tightly to the carotid and grows bilaterally, to the right and left of the heart, into the thorax; it is not connected, as was asserted previously, with the larynx of birds. Up to this developmental level in the animal kingdom the thyroids that do occur represent colloid glands; in old fishes and in birds parenchymatous forms seem to exist occasionally, but only in diseased animals. The colloid form is the normal one in these animals. Both forms, that is, colloidal and parenchymatous glands, appear for the first time in mammals. In these animals diet exerts a great influence; it could be demonstrated that a diet with "a high acid content" effects an increase of the parenchymatous glands; the same takes place as a result of internal disturbances of the acid-base equilibrium of the tissues. In the presence of alkalosis, however, the colloid thyroid was always preserved, and under certain conditions it developed into a colloid goiter.

Investigations on marmots and hedgehogs led to the conclusion that in all types of animals the thymus is concerned chiefly with the neutralization of acids; the thyroid, on the other hand, with the regulation of the oxygen supply. The relation between oxygenation of the respiratory air and the size of the thyroid was demonstrated by Duerst in correlation computation on cattle.

The etiologic factors in goiter in man were investigated on the basis of these investigations. Studies on gas metabolism disclosed two fundamental errors in the prevailing conception. Detailed analyses disclosed that an increase of 100 meters in altitude reduced the weight of the oxygen by about 1 per cent and that expansion due to heat reduces the weight by 0.4 per cent for each degree centigrade. For this reason the air in high mountains and that in tropical regions have almost identical oxygen deficiencies. At 300 meters above sea level and at an average temperature of 15 C. (59 F.), about 10 per cent of the normal sea level oxygen supply is missing. The hitherto accepted view that oxygen deficiency develops only above 3,000 meters altitude is absolutely erroneous on the basis of these investigations. A tendency to goiter formation is already evident in the presence of a 10 per cent oxygen weight loss. An entirely new discovery was made in the course of thousands of

air analyses, namely that carbon dioxide derives chiefly from the respiratory activity of the plant world. Assimilation in the green plant does not take place automatically as long as there is light but is absolutely elective, depending on adaptation (sun plants and shadow plants). Forest trees, for instance, assimilate, as a rule, for only about six hours daily, and they produce carbon dioxide by exhalation for eighteen hours. The heavy carbon dioxide that is produced at night sinks down, and on inclining terrain or by water attraction it produces currents and even carbon dioxide lakes. It was newly discovered that a chemical affinity exists between water and carbon dioxide, so that cold water, particularly if it flows rapidly, carries with it by its power of attraction such carbon dioxide currents and puts them into accelerated movement. This explains many of the edemic goiter regions which are found in river valleys, delta regions, swamps and so on, in which stagnant water, when it becomes warmer, again discharges carbon dioxide if calcium formation has not taken place. Thus goiters are prevalent in some heavily forested regions of Russia, Canada and North America.

Other climatic factors play a part, particularly fog, in which the carbon dioxide always increases. Winds from large forests, which frequently have continuously the same direction as the nocturnal mountain winds, often increase the carbon dioxide content in the lowest air layers and thus make breathing difficult and promote goiter formation.

Besides these chief causes of goiter formation the nutritional metabolism plays a part, particularly the modification of the acid-base equilibrium in the direction of a tissue acidosis; for instance, by a meat or sugar diet. Sugar has an elective affinity for potassium. By extensive experiments on domestic animals, Duerst found that potassium, even in the form of bicarbonate, is capable of dissolving the colloid in the goitrous colloid gland, whereas the calcium salts cause stasis and hardening of the colloid. This explains the surprising results obtained by Webster, who was able to produce parenchymatous goiters in rabbits only during the winter by feeding them with various types of cabbage, whereas during summer the same diet produced normal glands; this is explained by the fact that in winter the potassium and acid content of the various types of cabbage is especially high. Nutrition and particularly mineral substances are of great significance in the pathogenesis of goiter.

These studies also demonstrate the importance of minerals in the soil, which was stressed repeatedly by the Swiss surgeon Eugen Bircher.

Duerst regards the nature of the soil and water and the topographic location of a community as the chief reasons for the localization of endemic goiter regions. The carbon dioxide content plays a part, particularly if the carbon dioxide currents pass human habitations. It is of interest that in villages in which goiter is endemic many houses remain free from goiter whenever the ventilation is good and the house is not in the carbon dioxide current.

Duerst concurs with the observations of Eugster as regards the heredity of goiters. A genotypic heredity is excluded, but a transmission of the existing biochemical metabolic milieu is possible and, in view of the continuation of the causal circumstances, goiters and even cretinism continue to develop. It is also proved that a specific infection cannot exist. Topography, housing, hygiene and the nutritional factors have to be considered in the prophylaxis. As regards treatment, in addition to iodine, potassium bicarbonate can be used in colloid goiters. For toxic goiters a carbon dioxide reduction of about 15 per cent is recommended; that is, the persons in question should live at an altitude 1,500 meters above that to which they are accustomed. Conversely, in colloid goiter the regular daily inhalation of oxygen and potassium medication have a favorable effect; also dietetic measures that induce acidosis.

Deaths

Percy Lancelot Jones * Colonel, United States Army, retired, Erie, Pa.; University of Tennessee Medical Department, Nashville, Tenn., 1897; veteran of the Spanish-American War; on July 10, 1903, was appointed a first lieutenant in the medical corps of the United States Army and was sent to the Army Medical School, graduating in 1904; was advanced through the grades, given a temporary promotion to colonel in the World War and reached that permanent grade on July 10, 1929; retired on his own request on Oct. 30, 1931; fellow of the American College of Surgeons; aged 66; medical director of the Hamot Hospital, where he died, August 9, of carcinoma of the larynx.

Emerson Megrail * Cleveland; Western Reserve University School of Medicine, Cleveland, 1915; associate professor of hygiene and bacteriology at his alma mater and member of its teaching staff since 1919; consultant laboratory director of the division of health of Cleveland; served in France during the World War as a captain in the medical corps; member of the Society of Bacteriologists; fellow of the American Public Health Association; aged 51; died, October 21, of coronary thrombosis.

Elmon Reuben Johnson * Quincy, Mass.; Boston University School of Medicine, 1895; clinical instructor in laryngology at his alma mater from 1921 to 1928 and instructor in clinical laryngology and rhinology, 1928-1929; fellow of the American College of Surgeons; formerly served on the staff of the Massachusetts Memorial Hospital, Boston; otolaryngologist, Quincy City Hospital; aged 70; died, October 30, of cerebral hemorrhage and arteriosclerosis.

Harold Franklin Taylor, Hartford, Conn.; University of Vermont College of Medicine, Burlington, 1917; member of the Vermont State Medical Association; formerly assistant professor of medicine at his alma mater; served during the World War; associate medical director of the Aetna Life Insurance Company; aged 51; died, October 22.

Otto Joachim * New Orleans; Memphis (Tenn.) Hospital Medical College, 1883; member of the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; consultant in otolaryngology, Baptist and Orleans Tuberculosis hospitals, Milne Home and Touro Infirmary; aged 77; died, October 27.

Eugene Wilson Skelton, Brooklyn; Long Island College Hospital, Brooklyn, 1901; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; surgeon emeritus, Norwegian Hospital; president of the Baptist Home; aged 70; died, October 30, in the Methodist Hospital of cystic kidney and uremia.

William C. Schultz, Waynesboro, Pa.; Jefferson Medical College of Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; past president of the Franklin County Medical Society; aged 72; on the staff of the Waynesboro Hospital, where he died, October 29, of nephritis.

Charles Wardell Heywood * Utica, N. Y.; Northwestern University Medical School, Chicago, 1896; on the staff of St. Elizabeth Hospital; at one time on the staff of the Cook County Hospital and Hospital of St. Anthony De Padua, Chicago; aged 70; died, October 31, of coronary thrombosis.

Howard William Salisbury, Dearborn, Mich., University of Michigan Medical School, Ann Arbor, 1927; member of the Michigan State Medical Society; on the staff of the Emergency Hospital of the Ford Motor Company; aged 40; died, October 19, in the Henry Ford Hospital, Detroit.

John Freeman Summerville, Monroe, Pa.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; member of the Medical Society of the State of Pennsylvania; past president and secretary of the Clarion County Medical Society; aged 84; died, October 25.

Anthony Thomas Weber * Chicago; National Medical University, Chicago, 1907; veteran of the Spanish-American and World wars; formerly on the staffs of the Veterans Administration Facility in Hines, Ill., and Tucson, Ariz.; aged 64; died in October of coronary occlusion.

Alexander Bradfield, Tillamook, Ore.; Detroit College of Medicine and Surgery, 1933; member of the Oregon State Medical Society; county health officer; aged 34; died, October 28, in St. Vincent's Hospital, Portland, of agranulocytic angina following the use of dinitrophenol.

James M. Marsh, Elkhorn, Wis.; New York Homeopathic Medical College and Hospital, New York, 1890; past president of the Walworth County Medical Society; for many years city public health officer; aged 79; died, October 31, in the Walworth County Hospital of uremia.

Morrow Beach Wilson, National Military Home, Ohio; Starling Medical College, Columbus, 1895; veteran of the Spanish-American War; aged 70; died, October 24, in the Veterans Administration Facility, Dayton, of arteriosclerosis, heart disease and diabetes mellitus.

Clyde Frederick Zapf, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1918; was on the staffs of the Women's Homeopathic Hospital, Salvation Army Home and Hospital and the Hahnemann Hospital; aged 45; died, October 23, of angina pectoris.

Theodore Ora Morris, Los Angeles; Central College of Physicians and Surgeons, Indianapolis, 1904; served during the World War; on the staff of the Veterans Administration Facility, West Los Angeles; aged 63; died, October 19, in San Diego of coronary occlusion.

Edward Bailey Beasley, Ruxton, Md.; Johns Hopkins University School of Medicine, Baltimore, 1906; received the degree of doctor of public health from Harvard University, Boston, in 1911; aged 59; died, August 30, of coronary occlusion and arteriosclerosis.

Carroll Deane Smith, Paterson, N. J.; University of Texas School of Medicine, Galveston, 1925; member of the Medical Society of New Jersey and the National Gastroenterological Association; aged 42; died, October 28, at the Mount Sinai Hospital, New York.

Lucius Frank Laverty Jr. * Bay City, Mich.; Harvard Medical School, Boston, 1927; served in the Navy during the World War; on the staffs of the Bay City General Hospital and the Mercy Hospital; aged 46; was killed, October 30, in an automobile accident.

James Homer Butler, Lincoln, Ill.; Missouri Medical College, St. Louis, 1899; member of the Illinois State Medical Society; on the staffs of the Evangelical Deaconess Hospital and St. Clara's Hospital; aged 66; died, October 31, of carcinoma of the sigmoid.

Irvin Cameron Stayer, Woodbury, Pa.; Medico-Chirurgical College of Philadelphia, 1901; member of the Medical Society of the State of Pennsylvania; for many years member of the board of education; bank president; aged 68; died, October 24, of lymphosarcoma.

Jarold Elting Kemp, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1921; member of the Central Society for Clinical Research; on the staff of the Johns Hopkins Hospital; aged 43; died, October 19, of acute coronary occlusion.

John Michael Leonard * Fall River, Mass.; College of Physicians and Surgeons, Baltimore, 1900; for many years president of the staff of St. Anne's Hospital; medical inspector of public schools; aged 65; died, October 26, of carcinoma of the rectum.

Floyd Lamar Abernethy, Foley, Ala.; University of Alabama School of Medicine, University, 1916; member of the Medical Association of the State of Alabama; served during the World War; aged 50; died, October 29, of coronary occlusion.

Benjamin Eugene Sanborn, Manchester, N. H.; Dartmouth Medical School, Hanover, 1911; member of the New Hampshire Medical Society; on the staff of the Elliot Hospital; aged 56; died, October 3, of carcinoma of the rectum and liver.

Wilmington Eldrich Shallowhorne, Kerrville, Texas; Flint Medical College of New Orleans University, New Orleans, 1906; aged 60; on the staff of the Kerrville State Hospital, where he died, October 18, of chronic interstitial nephritis.

Frank Calhoun Smith, Washington, D. C.; Memphis (Tenn.) Hospital Medical College, 1896; served during the World War; formerly on the staff of the Veterans Administration; aged 68; died, July 8, in the Veterans Administration Hospital.

James G. Trant, Richmond, Va.; Medical College of Virginia, Richmond, 1906; member of the Medical Society of Virginia; for many years medical examiner for the city public school system; aged 60; died, October 29, of cerebral hemorrhage.

Joseph Collier Ray, Whitakers, N. C.; University College of Medicine, Richmond, 1909; member of the Medical Society of the State of North Carolina; aged 58; died, October 29, in the Rocky Mount (N. C.) Sanitarium of coronary heart disease.

Ray Wallace Moe, Peekskill, N. Y.; College of Physicians and Surgeons, Baltimore, 1903; past president of the board of the Peekskill Hospital; aged 61; died, October 27, of carcinoma of the lung and rheumatoid arthritis.

Lawson Henry Recher, Morocco, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879; member of the Indiana Medical Association; aged 85; died, October 11, of arteriosclerosis.

Joseph W. Maddox, Hillwood, Ala.; University of Tennessee Medical Department, Nashville, 1900; member of the Medical Association of the State of Alabama; aged 69; died, October 31, of coronary occlusion.

Louis James Loughlin, Carberry, Man., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1927; aged 39; died, October 31, in the Grace Hospital, Winnipeg, of gastric hemorrhage and pleurisy.

James T. Leigh, Du Quoin, Ill.; Missouri Medical College, St. Louis, 1882; member of the Illinois State Medical Society; on the staff of the Marshall Browning Hospital; aged 83; died, October 30, of senility.

Everett Lamont Bradley @ Pontiac, Mich.; George Washington University School of Medicine, Washington, D. C., 1920; aged 46; died, October 30, in the Pontiac General Hospital of acute hemorrhagic pancreatitis.

Edward P. Condon, Spokane, Wash.; John A. Creighton Medical College, Omaha, 1910; aged 56; died, October 23, of cerebral hemorrhage, pneumonia, coronary thrombosis and arteriosclerosis.

John Todd, Newport, Ky.; Medical College of Ohio, Cincinnati, 1900; member of the Kentucky State Medical Association; formerly health officer; aged 64; died, October 21, of heart disease.

McClellan Wilson, McAlester, Okla.; Ensworth Medical College, St. Joseph, Mo., 1894; member of the Oklahoma State Medical Association; aged 77; died, October 15, of cerebral hemorrhage.

Leonard H. Jacobsen @ Seattle; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; aged 60; died, October 4, of recurring coronary thrombosis and cholecystitis.

James Brown McClendon, Birmingham, Ala.; Rush Medical College, Chicago, 1933; member of the Medical Association of the State of Alabama; aged 33; died, October 29, of heart disease.

Horace Fleckenstine @ Newportville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; aged 63; died, October 31, of diabetes mellitus and cardiorenal disease.

John Milton Boyd @ Washington C. H., Ohio; Starling Medical College, Columbus, 1904; aged 82; died, October 28, in the White Cross Hospital, Columbus, of cerebral hemorrhage.

Bela David Thomas, Dallas, Texas; Kansas City (Mo.) College of Medicine and Surgery, 1917; served during the World War; aged 56; died, October 12, of coronary occlusion.

Jacob A. Wagner, Bland, Va.; Medical College of Virginia, Richmond, 1901; for many years superintendent of the county schools; aged 80; died, October 15, of pernicious anemia.

Charles Herbert Sangster, Buffalo; University of Buffalo School of Medicine, 1895; for many years principal of several city schools; aged 82; died, October 20, of myocarditis.

Clarence Harmon Ellis, Phoenix, Ariz.; Homeopathic Hospital College, Cleveland, 1887; aged 81; died, October 13, in the Good Samaritan Hospital of coronary occlusion.

Ralph Dwight Quillen, Baltimore; College of Physicians and Surgeons, Baltimore, 1909; aged 57; died, October 20, in a local hospital of arteriosclerosis and heart disease.

Alfred Daudelin, Nashua, N. H.; Baltimore Medical College, 1908; member of the New Hampshire Medical Society; aged 63; died, September 13, of cardiorenal disease.

Thomas Art Smith, Charlotte, N. C.; North Carolina Medical College, Charlotte, 1917; aged 51; died, October 18, in the Mercy Hospital of coronary thrombosis.

Theodore Lincoln Hazard, Iowa City, Iowa; University of Michigan Homeopathic Medical School, Ann Arbor, 1883; aged 81; died, October 31, of heart disease.

Wyatt S. Miles, Crockett, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1890; aged 75; died, October 9, of cerebral hemorrhage.

George H. Craft, Newark, N. Y.; University of Buffalo School of Medicine, 1896; aged 67; died, September 1, of cerebral hemorrhage and arteriosclerosis.

Charles Clinton Cooley, Chicago; Jenner Medical College, Chicago, 1915; also a dentist; aged 60; died, October 12, in Warrenville, Ill., of coronary thrombosis.

Jane Kelsey Todd, Portland, Ore.; Northwestern University Woman's Medical School, Chicago, 1898; aged 73; died, October 3, of myocarditis and pneumonia.

John Ignatius McGonigle, Oklahoma City; Beaumont Hospital Medical College, St. Louis, 1901; aged 75; died, October 10, of coronary thrombosis.

Eugene A. Woods, Sarasota, Fla.; University Medical College of Kansas City, Mo., 1898; aged 65; died, September 27, of fibroid pulmonary tuberculosis.

John A. Rickert @ Allegan, Mich.; Detroit College of Medicine and Surgery, 1921; aged 46; died, October 9, in Detroit of chronic myocarditis.

James Bones Wright, Augusta, Ga.; University of Georgia Medical Department, Augusta, 1888; aged 79; died, October 8, of cardiovascular renal disease.

William Ladell Edgar @ Athol, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1894; aged 68; died, October 11, of endocarditis.

Albert D. Mock, Marion, Ind.; Curtis Physio-Medical Institute, Marion, 1888; aged 76; died, October 24, of myocarditis and arteriosclerosis.

John B. Kersey, Cincinnati; Pulte Medical College, Homeopathic, Cincinnati, 1885; aged 79; died, October 23, of carcinoma of the intestine.

H. W. Glasscock, Smithfield, Ky.; University of Louisville (Ky.) Medical Department, 1875; aged 85; died, October 10, of coronary occlusion.

Andrew Charles Callahan, Buffalo; Ohio Medical University, Columbus, 1905; aged 60; died, October 11, of myocarditis and coronary sclerosis.

William S. Frye, New Kensington, Pa.; Physio-Medical College of Indiana, Indianapolis, 1882; aged 82; died, October 30, of arteriosclerosis.

Otto L. Von der Au, St. Louis; Beaumont Hospital Medical College, St. Louis, 1892; aged 71; died, October 4, of cerebral hemorrhage.

Charles Joseph Sager, Woodstock, Va.; Medical College of Virginia, Richmond, 1898; aged 68; died, October 24, of cerebral hemorrhage.

Vernon Leslie Litsinger, Farnham, Va.; Maryland Medical College, Baltimore, 1912; aged 58; died, October 14, of heart disease.

William Wylie Nasmyth, Sylvan Lake, Alta., Canada; Trinity Medical College, Toronto, Ont., 1889; aged 75; died, September 6.

Homer Burton Curtis, Kansas City, Mo.; Barnes Medical College, St. Louis, 1901; aged 69; died, October 2, of cerebral hemorrhage.

Frank Joseph Schwarz @ St. Louis; Bennett Medical College, Chicago, 1915; aged 64; died, October 28, of bronchopneumonia.

Charles Cornelius Langsdorf, Seffner, Fla.; Bellevue Hospital Medical College, New York, 1894; aged 73; died, October 7.

George Hal Williamson, Port Austin, Mich.; Chicago College of Medicine and Surgery, 1913; aged 56; died, October 18.

Joseph Watkins Yard, Long Beach, Calif.; Bellevue Hospital Medical College, New York, 1884; aged 83; died, October 27.

George Allan Anderson, Calgary, Alta., Canada; Trinity Medical College, Toronto, Ont., 1900; aged 71; died, September 27.

Michael Krantz @ Boston; Middlesex University School of Medicine, Waltham, Mass., 1921; aged 59; died, September 4.

James Edwin Blickensderfer, Lebanon, Mo.; Barnes Medical College, St. Louis, 1896; aged 74; died, October 19.

Claxton Perry Binford, Huntsville, Ala.; Meharry Medical College, Nashville, Tenn., 1927; aged 41; died, October 3.

James Guard Fisk, Venice, Calif.; Medical College of Indiana, Indianapolis, 1892; aged 73; died in September.

Correspondence

TRANSFUSION OF BLOOD AND BLOOD SUBSTITUTES

To the Editor:—In the editorial "Transfusion of Blood and of Blood Substitutes" (THE JOURNAL, Nov. 8, 1941, p. 1627) you state that "Hustin of Belgium proposed in 1914 a method of collecting blood in a vessel containing an equal amount of a solution of 5 per cent dextrose in 9 per cent of sodium chloride and sodium citrate in the amount of 20 cc. for each hundred cubic centimeters of blood. The method was used on a rather large scale by the Entente forces during World War I."

It is correct that Hustin was the first to try sodium citrate in blood transfusion. However, he thought that in order to prevent coagulation it was necessary to use strongly diluted blood. He mixed (Note sur une nouvelle methode de transfusion, *Bull. Soc. roy. d. Sc. méd. de Bruxelles* 72:104 [April 6] 1914) 150 cc. of blood with 150 cc. of a dextrose-sodium citrate solution. Thus for a blood transfusion of average size (500 cc.) an equal amount (500 cc.) of dextrose-sodium citrate solution had to be added. It is perfectly clear that blood in such strong dilution loses the vital qualities of pure blood. Furthermore, the introduction of a quart of fluid might overtax the circulation.

As far back as 1918 Hédon (Note complémentaire sur la transfusion du sang citraté, *Presse méd.* 26:57 [Jan. 31] 1918) pointed out that "Hustin's method was really an infusion of a strongly diluted blood mixed with sodium citrate and dextrose."

The citrate method of blood transfusion became a practical method and was used, as you state in your editorial, on a rather large scale in World War I, when Agote (Nuevo procedimiento para la transfusion del sangre, *An. Inst. Modelo de clin. méd.*, January 1915) and I (A New and Greatly Simplified Method of Blood Transfusion, *New York M. Rec.* 87:141 [Jan. 23] 1915) independently and contemporaneously showed that addition of a small quantity of citrate solution was sufficient to prevent coagulation of the blood. I used 50 cc. of a 2.5 per cent solution for 450 cc. of blood and Agote used 5 cc. of a 25 per cent stock solution.

Neither Agote nor I knew of Hustin's work when we published the description of our methods. The World War had started in August 1914 and interrupted exchange of medical literature between Europe and this country.

Hustin's work presented an interesting experiment but not a solution of the problem. For this reason it cannot deserve more than a certain historical interest.

RICHARD LEWISOHN, M.D., New York.

"THERE IS NOTHING PHYSICALLY THE MATTER" (CONTINUED)

To the Editor:—Dr. Roy Grinker's communication in THE JOURNAL, October 18, deserves wide attention and comment. The physician's attitude toward patients with nervous symptoms generally reflects discredit on the medical profession. The reasons for that attitude should give us pause.

Most physicians have little difficulty in recognizing anxiety states and the various organ neuroses. Even when the diagnosis is made by the exclusion method alone, our correct percentages are satisfactorily high. However, when a diagnosis of psychoneurosis has been established there seems often to be little advice that can be given which is of real or lasting benefit. The patient is usually left more confused than ever, for he is frequently told, against his own better judgment, that "there is nothing physically the matter" or "nothing seriously wrong." Both of these considered opinions are erroneous. Nervous disorders are invariably accompanied by measurable disturbances

of physiology. At first functional and reversible, these disturbances readily persist and cause structural organic diseases that are demonstrable by physical and laboratory examinations.

As physicians, we dislike and dismiss "neurotics" because we are not equipped by instruction or experience to treat them. They often represent our failures: the skeletons in our medical closets. It takes much time to listen to their many complaints, patience to brook their "resistance" and a very definite plan to combat their aggressiveness and lead them away from an emotional to a rational and realistic outlook on life. Yet these hardships are a part and parcel of our heritage as physicians. If we cannot find time or heart for this phase of our work, the least that we can do is to recognize our responsibility and reputation as physicians and instruct the patient as to where advice may be found.

Medicine knows no limits to its objectives; those objectives are to improve the total health and welfare of all the people. Neither in their own nor in the public's eyes do physicians restrict their capacity to give generous advice. The healing of the sick is a science that can exclude no part of the body. Must it continue to be said of us after twenty-four hundred years of science that "it is the great error of our day in the treatment of the human body that physicians separate the soul from the body"? So neglectful and indifferent an attitude will deprive us of that confidence which our many sacrifices have shown us to deserve and deny hope to many sick people who may reasonably expect hope from rational and courageous treatment.

ANDREW D. HART JR., M.D., Charlottesville, Va.

HEALTH OF SHARECROPPERS

To the Editor:—The article in THE JOURNAL, July 5, by Dr. J. W. Thompson on the clinical status of a group of Negro sharecroppers provokes discussion. An evaluation of the health of Negro sharecroppers is made on the basis of a sample of 24 subjects on whom a history was taken and a physical examination made. The data gleaned by the author seemed to indicate a dangerous state. Yet he concludes that he doubts that the "Negro sharecroppers are apt to be in a lamentable state of ill health." Finally he states that all but 1 were in good general condition and not far below the excellence found in a group of Harvard students—who did not show a single abnormal finding.

I recapitulate Dr. Thompson's observations: pyorrhea in 50 per cent, syphilis in 8 per cent, pellagra in 4 per cent, pulmonary signs—not investigated—in 8 per cent, possible heart disease in 4 per cent, gonorrhea in 63 per cent and gonorrheal arthritis in 12 per cent.

Infant mortality figures were five times as great as those among white persons. The group was 10 per cent under ideal weight and 4.5 per cent under ideal height.

As a supererogatory gesture the author quotes another piece of research to show that Negroes can endure hard labor better than the white race.

A sincere interest in the health of Negro sharecroppers demands an excellence of medical research.

JOSEPH M. KRIMSKY, M.D., Brooklyn.

[This letter was referred to Dr. John W. Thompson, Toronto, who replies:]

To the Editor:—The two serious diseases which were found prevalent in the histories of the Negro sharecroppers were gonorrhea and malaria. All these subjects had been under medical care and, as far as one could determine, had been cured. That they had been adequately treated and had recovered is not deplorable. Two subjects showed positive Wassermann reactions, and 1 of these was not a sharecropper. However, accept-

ing the figure of 8 per cent, Roberts and Williams (*South. M. J.* 30:458 [May] 1937) report an incidence of 11.7 per cent in the white population of Gibson County in Tennessee, and Usilton (*Pen. Dis. Inform.* 16:147 [May] 1935) estimates that 8 per cent of males from 20 to 30 years of age contract syphilis. I cannot regret the fact that the figure for the Negroes is, if anything, lower than that for the white population. That the cardiac and respiratory signs found on clinical examination were without significance was shown by the excellent ability of these subjects to transport oxygen—a performance which is quite incompatible with either cardiac or respiratory disease. That the infant mortality was five times as great as that found in the "control" series is indeed a large difference but scarcely one which would necessarily damage the health of the surviving members to which the article had reference. As to weight, it would be more correct, in all probability, to state that the Harvard students were 10 per cent above rather than that the Negro was 10 per cent under ideal weight; the difference in weights is what one might expect between groups composed of sedentary individuals, on the one hand, and physically active individuals on the other. I can say nothing with reference to the difference of 8 cm. in the relative heights other than to suggest as an explanation a difference in anthropologic characteristics and to confess ignorance as to its diagnostic significance. In order to determine the physical fitness of an individual there is obviously no better way than to measure his capacity to perform a task whose standard of execution is known to be commensurate with physical fitness. This was done with the Negro whose performance would be the envy of those desirous of being fit. If reference to this fact is looked on as a "supererogatory gesture," its significance has not been understood.

JOHN W. THOMPSON, M.B., University of Toronto.

DIETARY HEALING OF DENTAL CARIES

To the Editor:—In *THE JOURNAL*, September 27, the editorial on dietary healing of dental caries seems to be misleading and not in conformity with the article from which the information was secured. To quote from *Science* of June 27, 1941: "The dentine had a sclerotic appearance and beneath every place where the outer part of the tooth had been subjected to attack a new, thick layer of secondary dentine had been laid down. . . ." This statement is quite different from the one made in the editorial—"the exposed tooth was found covered by a thick layer of secondary dentine more or less filling the earlier cavity."

HOUGHTON HOLLIDAY, New York.

Associate Dean, School of Dental and Oral
Surgery of Columbia University.

To the Editor:—In the September 27 issue, page 1099, appears an editorial entitled "Dietary Healing of Dental Caries." The opinions clearly reveal that some one has disseminated misleading interpretations of a physiologic process previously described.

A careful reading of Sognnaes' paper in *Science* reveals a tendency on the part of the author to wishful thinking when he applies the term reparative process to what is obviously the deposition of secondary dentin. The person who wrote the editorial certainly went Sognnaes one better with his statement that secondary dentin more or less filled the earlier cavity. Secondary dentin forms in all rats' teeth subject to wear and frequently in rats' teeth that are not subject to wear, regardless of the presence or absence of dental caries. Hoffman and Schour (*Am. J. Orthodontics* 26:854 [Sept.] 1940) have described this process in mathematically exact terms. Their work, coupled with mine, explain what happened to Sognnaes' carious process: it was worn off when the diet was changed, not repaired or healed; the dentin that remained was secondary

dentin or uninjured primary dentin. Hoffman makes the statement that this process is not common in human teeth. To sum up, at the present time no one has adequately demonstrated that carious lesions may be repaired or healed or that regenerative processes take place in necrotic dentin.

S. S. ARNIM, Richmond.

School of Dentistry Medical College of Virginia.

NOTE.—It was shown in 1936 by Arnim and his associates (Arnim, S. S.; Clarke, M. F.; Anderson, B. G., and Smith, A. H.: Dental Changes in Rats Consuming Diet Poor in Inorganic Salts, *Yale J. Biol. & Med.* 9:117 [Oct.] 1936) of Yale University that alterations in the internal histologic structure of the molar teeth of rats are produced by diets deficient in phosphorus, calcium and other inorganic salts. Initial reparative processes were described following the addition of adequate mineral salts to the deficiency diets. The essential point in Sognnaes' paper "Dietary Repair of Experimental Caries" (*Science* 93:617 [June 27] 1941) is his description of an even more effective reparative process in externally produced dental caries when the carious rats are placed on a non-caries producing luxury diet. Whether or not the two reparative processes are identical cannot be told without additional histologic study. It should be emphasized, however, that both investigators worked with rapidly growing young rats.—En.

WEIL'S DISEASE

To the Editor:—In referring to your editorial on Weil's disease (*THE JOURNAL*, Oct. 11, 1941, p. 1266), permit me to make one suggestion. In speaking of the laboratory tests in the diagnosis, the editorial states that ". . . dark field examination of centrifuged blood during the first stage and of the urine after the tenth day are the most important." Unfortunately, in practice the pitfalls involved in the direct examination of blood by dark field illumination are such that little reliance can be placed on this method alone, even by experienced laboratory workers.

Recently I had occasion to speak with Dr. E. A. Fennel of Honolulu on this very subject. I had just completed a study on canine leptospirosis (*Canine Leptospirosis in Pennsylvania, J. Infect. Dis.* 69:131-137 [Sept.-Oct.] 1941). In this study numerous blood specimens were examined serologically (agglutination-lysis test) and also by direct dark field illumination of centrifuged blood for evidence of leptospirosis. Fortunately, it was early decided that what it was thought were *Leptospira* in many instances were actually filaments of red blood cell or of platelet origin. Dr. Fennel and his co-workers had a similar experience in Hawaii (Weil's Disease and Artefacts, *Proc. Staff Meet. Clinic, Honolulu* 4, March 1938). During an extensive study of human leptospirosis, the great number of positive reactions as demonstrated by dark field illumination of blood became alarmingly suggestive. This led to a thorough investigation in which normal controls were used. Finally it was decided that they were dealing with artefacts possibly derived from fibrin shreds, platelets, red cell stroma or reticulum. It was Dr. Fennel's conclusion that it was dangerous to make a positive diagnosis of Weil's disease by dark field examination of blood or urine of patients unless supported by confirmatory evidence (i. e. animal inoculation of blood or urine at the proper stage of the disease). Recent studies have demonstrated that the agglutination-lysis test on the patient's serum, beginning with the tenth day of the disease, is probably a quicker means to a diagnosis than animal inoculation—guinea pigs rarely show evidence of the disease, show jaundice or succumb to the infection before a week or ten days from the time of inoculation.

CLARA RAYEN, M.D., Youngstown, Ohio.

serious injury. Subsequently the plaintiff sued the defendant physician, the assistant surgeon who had supervised the operation performed by the intern, for damages, and from an adverse judgment he appealed to the Supreme Court of Errors of Connecticut.

The plaintiff contended that the defendant, having been present at and assisted in the operation, was guilty of gross misconduct in failing to render adequate after-care to the plaintiff and in allowing the after-care to pass into the hands of other physicians. The plaintiff, said the Supreme Court of Errors, to recover must prove that the defendant failed to exercise the degree of care, skill and diligence ordinarily exercised by physicians and surgeons in the same line of practice in the general neighborhood of Hartford. Since there was no claim of negligence in connection with the operation itself, the plaintiff must show that the defendant was under some legal obligation to treat the patient after the operation and that he failed to satisfy that obligation. The evidence showed that the defendant was regularly on duty in the women's ward, not the ward in which the plaintiff was a patient. He had been assigned merely to assist the intern and "except for being present at the operation had no connection with the plaintiff's care or treatment." When the operation was over, the plaintiff was returned to the care of the physician in charge of his own ward. There was no special contract whereby the defendant agreed to treat the plaintiff during his hospitalization. A surgeon who assists at an operation, continued the Court, is not, in the absence of a specific contract, liable for the rendering of after-care. In such a case the surgeon may rely on the custom of the hospital in divorcing the operation from the after-care. Furthermore, in this day and age when it is well known that there are physicians and surgeons of special skill in particular branches of their profession, it cannot safely be announced as a general rule of law, applicable to a case of this nature, that a surgeon who performs an operation is liable for the negligence of other physicians, nurses or interns in hospitals in the after-treatment unless the evidence shows that he specially undertakes such employment. The judgment for the defendant was accordingly affirmed.—*Sheridan v. Quarrier*, 16 A. (2d) 479 (Conn., 1940).

Malpractice: Alleged Erroneous Diagnosis of Gonorrhea.—One of the plaintiffs consulted the defendant physician relative to an itching in the region of her vagina. The physician took her history, made a smear from the vagina, urethra and cervix and after a microscopic examination of the smear (referred to in the reported decision as the methylene blue test) made a diagnosis of gonorrhea and so informed his patient, asking that her husband, the other plaintiff, consult him. The physician then instituted sulfanilamide therapy on the wife. When the husband consulted the physician, the physician was unable to obtain a smear from the entrance of the husband's urethra but "obtained an imprint" which did not reveal evidence of gonorrhea on microscopic examination. He informed the husband that he doubted whether he had gonorrhea but advised immediate treatment. The husband, however, never returned for treatment. Later both plaintiffs consulted another physician, who made smears and sent them to a laboratory for examination, which after making a test referred to in the reported decision as a "gram negative stain" test reported "negative" specimens. Then the second physician determined that neither the husband nor the wife had gonorrhea. The plaintiffs thereafter sued the defendant physician for malpractice. Shortly after the institution of the action the defendant physician sent the slide containing the smear he had taken from the wife to two laboratories, both of which performed the "gram negative stain" test and reported a "positive reaction showing gonococci." From a judgment in favor of the physician the plaintiffs appealed to the district court of appeal, second district, division 2, California.

The first question for the appellate court's determination was whether the evidence before the trial court was sufficient to sustain a judgment in favor of the physician and against the wife. A physician and surgeon, said the court, is not required to make a perfect diagnosis but is required to have only that degree of skill and learning ordinarily possessed by physicians

of good standing practicing in the same locality and to use ordinary care and diligence in applying that learning to the treatment of his patient. The evidence in this case discloses that it was the ordinary practice of physicians and surgeons in the community in which the defendant physician practiced in making a diagnosis of gonorrhea to use either the methylene blue test or the gram negative stain test. In this case the evidence discloses that at the time the wife consulted the defendant physician he made the methylene blue test, which showed the patient suffering from gonorrhea. Subsequently, the same slides were submitted by him to two independent laboratories where gram negative stain tests were made showing the presence of gonococci. It therefore appears that there was substantial evidence to support the finding of the trial court that the defendant physician had used the requisite skill in diagnosing the wife's complaint, and a judgment in favor of the physician was proper.

The next question the court was called on to determine was whether or not the evidence before the trial court was sufficient to sustain a judgment in favor of the physician and against the husband. The appellate court concluded likewise that the judgment in favor of the physician was proper. The evidence is clear, said the court, that the physician after examining the husband told him that he did not think he was suffering from gonorrhea but recommended that he return for further examination and treatment, which the husband refused to do. Obviously the physician's conduct relative to the husband was proper and not actionable.

For the reasons stated, the judgment in favor of the physician was affirmed.—*Ries v. Reinard*, 117 P. (2d) 386 (Calif., 1941).

Intoxication: Refusal of Defendant to Submit to Blood Test Admissible in Evidence.—The fact, said the Supreme Court of Iowa, that a defendant accused of operating a motor vehicle while intoxicated declined shortly after his arrest to submit to a blood test to determine whether or not he was intoxicated is admissible in evidence and may be considered by the jury as a circumstance, with all other facts and circumstances developed at the trial, in determining whether or not he was intoxicated at the time in question. While a defendant cannot be compelled to testify, under the practice in Iowa courts his refusal to testify can be considered and commented on. If he cannot be compelled to submit to a blood test, it is because he cannot be compelled to give evidence. Since his refusal to give evidence by testifying can be considered, his refusal to give evidence by submitting to a blood test can likewise be considered. The Iowa constitution contains no express provision prohibiting self incrimination, and the only constitutional provision that would appear to guarantee such protection is the due process clause, which in the opinion of the court does not render inadmissible testimony that the defendant refused to submit to a blood test. It is proper, continued the court, to show the defendant's conduct, demeanor and statements, whether oral or written, his attitude and relations toward the crime, if there was one, and the weight of these circumstances is for the jury to determine. The fact that the defendant declined to submit to a blood test is such a circumstance as may be shown for the consideration of the jury.—*State v. Benson*, 300 N. W. 275 (Iowa, 1941).

Society Proceedings

COMING MEETINGS

- Annual Congress on Industrial Health, Chicago, Jan. 12-13. Dr. C. M. Peterson, 535 North Dearborn St., Chicago, Secretary.
- American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Diveley, 1103 Grand Ave., Kansas City, Mo., Secretary.
- American Association for the Study of Neoplastic Diseases, Washington, D. C., Dec. 18-20. Dr. Eugene R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- Puerto Rico, Medical Association of, Santurce, Dec. 11-14. Dr. David E. Garcia, P. O. Box 3866, Santurce, Secretary.
- Society of American Bacteriologists, Baltimore, Dec. 29-31. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Southern Surgical Association, Pinehurst, N. C., Dec. 9-11. Dr. E. M. Ochsner, 1430 Tulane Ave., New Orleans, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Annals of Internal Medicine, Lancaster, Pa.

15:347-628 (Sept.) 1941

- Blood Pressure Reducing Property of Extracts of Kidneys in Hypertensive Patients and Animals. I. H. Page, O. M. Helmer, K. G. Kohlstaedt, G. F. Kempf, W. D. Gambill and R. D. Taylor, Indianapolis.—p. 347.
- Results from Management of Bleeding Gastric and Duodenal Ulcer. T. G. Miller, Philadelphia.—p. 390.
- *Weil's Disease: Report of Six Cases. H. K. Rathbun and J. M. Waghelstein, Baltimore.—p. 395.
- Diagnosis and Management of Brucellosis. W. M. Simpson, Dayton, Ohio.—p. 408.
- Sulfonamide Therapy of Staphylococcal Septicemia. R. G. Torrey, Philadelphia; L. A. Julianelle, St. Louis, and H. G. McNamee, Philadelphia.—p. 431.
- Value of Sternal Marrow Aspiration as Method of Bone Marrow Biopsy. E. H. Falconer and M. E. Leonard, San Francisco.—p. 446.
- Changes in Cardiac Shadow Following Pharmacologic "Shock" Therapy of Schizophrenia. H. W. Sterling, Little Rock, Ark., and C. N. Baganz, Lyons, N. J.—p. 459.

- Responsibility of American College of Physicians for Postgraduate Training. E. L. Bortz, Philadelphia.—p. 582.

Weil's Disease.—Rathbun and Waghelstein suggest that in this country Weil's disease would probably be diagnosed more frequently if the illness were considered in the differential diagnosis of jaundice of unknown cause or any obscure illness characterized by muscle pains, conjunctivitis and sudden unexplained fever. The final diagnosis rests on the results of the laboratory procedures. Agglutination reactions and guinea pig inoculations with blood and urine are diagnostic aids. The history of contact with the urine of wild rats is a valuable aid. Leukocytosis and albuminuria are important points in differentiating Weil's disease from catarrhal jaundice. Probably the most noteworthy feature of the disease is the extreme apathy of the patients. This was an outstanding characteristic of 4 of the 6 patients whom the authors encountered within twenty months. One patient admitted with jaundice and azotemia was thought to be suffering from acute yellow atrophy, suggesting that any similar patient with jaundice of unknown cause should be thoroughly investigated for the possibility of Weil's disease. Age, cardiac function and the presence or absence of uremia and jaundice influence the prognosis. The older the patient the more grave the prognosis. The fatality rate for patients without jaundice is negligible. Uremia has an unfavorable influence on the prognosis, particularly if oliguria or anuria is present. An active immunity may be produced by the injection of killed organisms, and Inada and his associates reduced the fatality rate from 30.6 to 17.3 per cent with immunized horse and human convalescent serums. A high carbohydrate-low fat diet might prove beneficial in the treatment of patients with jaundice.

Symptomatic Hemolytic Anemia.—Singer and Dameshek present 7 cases of benign and malignant neoplasms concomitant with hemolytic anemia, or symptomatic hemolytic anemia. The symptoms and signs of the anemia are a combination of the

hemolytic process and the underlying disease. The associated diseases in their 7 patients were dermoid cyst, chronic lymphatic leukemia, Hodgkin's disease, lymphosarcoma, severe hepatic disease and pneumonia with a panagglutinin. Spherocytosis and increased hypotonic fragility are often present in cases of symptomatic hemolytic anemia, although a "pseudomacrocytic" blood picture may be present. The spherocytosis may mean that the abnormality is due to undefined hemolyzing agents. The recognition of these cases is of importance in evaluating the type of anemia present in certain cases of lymphomatous disease and in ruling out an "idiopathic" hemolytic process. Splenectomy may be valueless, but treatment of the underlying process may be curative. The recognition of these cases further supports the hypothesis that various hemolytic agents, usually acting through the spleen, are responsible for hemolytic anemias.

Bleeding Peptic Ulcer.—Walters and Cleveland state that their results with partial gastrectomy performed during 1932 to 1936 inclusive support the premise that this operation offers the best chance of cure or amelioration of symptoms of bleeding peptic ulcer and the best prophylaxis against further hemor-

rhage. When the procedures which have proved of least merit are eliminated results should be improved. Thus, among the 119 patients who had resections in 1940 for bleeding peptic ulcer the pyloric antrum was removed in all but 1 and the posterior Pólya type of resection and anastomosis was employed in 94.1 per cent. The 1940 results should be superior. During the 1932 to 1936 period, seven pyloric antrums were not removed and only 75 per cent of the partial gastrectomies were of the posterior Pólya type.

Carcinoma of Pancreas.—Schnedorf and Orr review the records of the 35 cases of primary carcinoma of the pancreas and the 17 of the ampulla of Vater encountered at the University of Kansas Hospitals during the last twenty years. Only cases in which the diagnosis was proved at necropsy or by surgical biopsy are included. The disease was rapidly fatal in most patients. Thorough study of the function of the pancreas is advisable for the diagnosis of an early obscure cancer of the pancreas or of the ampulla of Vater in all patients with inexplicable abdominal complaints. Radical resection offers the only hope for cure. Palliative operation is indicated in cases of advanced disease. Fatty infiltration and hepatic degeneration were found at necropsy in 10 of the 52 patients. On the basis of experimental evidence the feeding of lecithin, choline, pancreatic extract or lipocaic is indicated in the preoperative and postoperative treatment of such patients to prevent fatty changes in the liver and to maintain life.

Chronic Ulcerative Colitis.—As a result of their study of the problem of chronic ulcerative colitis carried on in the departments of surgery, bacteriology and medicine of the University of Chicago during the last eight years Dragstedt and his associates are convinced that *Bacterium necrophorum* plays an etiologic role in the disease. They present the following evidence in support of their contention: 1. It is the predominant organism in the isolated colon in ulcerative colitis during exacerbations, and it disappears during periods of spontaneous quiescence. 2. It has been found in most cases of typical ulcerative colitis. 3. Specific antibodies for it have been found in the blood of patients with chronic ulcerative colitis and not in the blood of normal persons. 4. The organism is pathogenic for rabbits. 5. The literature indicates that it is similar to if not identical with *Bacillus* or *Bacteroides funduliformis*, repeatedly associated with necrotic lesions of the mucous membranes in man and with *Bacillus necrophorus*, which is believed to cause various necrotic lesions in domestic animals. *Bacterium necrophorum* is probably present in the normal alimentary tract of man and monkeys and requires some additional factors producing necrosis of the mucosa to furnish conditions suitable for its growth.

Wound Healing and Ascorbic Acid.—Lund and Crandon studied the effect that preoperative diets and plasma vitamin C levels had on the postoperative healing of abdominal wounds. Postoperative hernias or disruptions are the result of poor healing. Of 58 patients who returned to the follow-up clinic from three months to one year after discharge 9 had hernia. Those with low preoperative plasma levels showed a larger percentage of hernia than did those with high levels. The same was true of patients with small amounts of the vitamin in their preoperative diets. However, low plasma values do not always mean depleted reserves, but the wounds of all patients with higher values should heal in so far as ascorbic acid is a factor in their healing. The disrupted wounds of 12 patients have been studied. Despite the low vitamin levels of 8 patients scurvy played no part in the disruption. The vitamin C reserves of 3 of the 4 remaining patients were severely depleted, and scurvy probably delayed or prevented the healing of their wounds. The main cause of the accident in the last patient was undoubtedly sepsis and not scurvy. The data suggest that a larger part of the problem of disruption will be solved by an improved suturing technic than will be solved by studies of or treatment with vitamin C. However, the fact that in a few instances disruption occurs in conjunction with severely depleted vitamin C reserves indicates that these reserves should be studied preoperatively and that if they are low proper treatment should be instituted.

Subdural Hygroma.—Da Costa and Adson report the case of a boy aged 9 years who had been thrown from his pony two days prior to admission to the Mayo Clinic. He regained consciousness in about an hour after he was found but continued drowsy and vomited. At a hospital it was determined that his left arm and leg were partially paralyzed. The mother stated that the paralysis was less severe when he regained consciousness. During the night of the first day in the hospital the boy could be aroused, although he was drowsy. The vomiting ceased. The following day the left arm and hand appeared to be weaker. The drowsiness had abated somewhat. He had hemiparesis of the entire left side, including the face. An exploratory operation through a temporal decompression was performed. On perforation of the dura, blood-tinged cerebrospinal fluid spurted out, and further opening revealed a large pool of blood-tinged fluid between the dura and the arachnoid compressing the temporal, parietal and frontal lobes on the right side. The rent in the arachnoid was in the region of the sylvian fissure and from it more cerebrospinal fluid could be seen escaping. Approximately 4 ounces (120 cc.) of cerebrospinal fluid was removed when pulsations in the cerebral artery could be seen. To remove

any subsequent collection of fluid while the ventricles refilled and the brain was being replaced, a Penrose wick was inserted into the wound and left in place for four days. During this time fluid intake was encouraged. Convalescence was uneventful. On the eighth postoperative day normal function had returned to the foot and the arm. Full function of the face and the hand returned by the ninth postoperative day. He was dismissed on the fifteenth day with full function, except a slight incoordination of his fingers and a slight limp on walking alone. A subsequent report indicated that the boy had recovered completely.

Fibroadenoma of Breast.—Owens and Adams discuss the gross and microscopic features of "cystosarcoma phyllodes." They report a case of their own and summarize the 12 cases reported since 1931, when Lee and Pack collected 105 from the literature and added 4 personal cases. A list of the various names applied to the tumor is given, and the authors believe that the simple descriptive term "giant intracanalicular fibroadenoma of the breast" should be accepted.

Surgical Jaundice and Yellow Atrophy.—Olwin determined the prothrombin level in 62 patients with jaundice and found that in patients with obstruction of the common duct it varies widely, depending on the duration of the jaundice and on general nutrition and diet. In nearly all these patients, except those who had jaundice in the later stages, the prothrombin level after vitamin therapy was near normal in one to four days. However, only a small percentage of patients with hepatic cirrhosis, if hepatic damage is not too severe or has not been present too long, will show some response to vitamin K therapy even after intensive and prolonged vitamin and bile salts therapy. The results indicate that rather than the original prothrombin level the response of the liver to vitamin K as reflected in the prothrombin rise is the important point in the measurement of hepatic function. To eliminate absorption of vitamin K from the gastrointestinal tract the vitamin is given intravenously. If the original prothrombin determination is low 2 mg. of menadione is given intravenously and the prothrombin level is rechecked after twenty hours. If it is still below 100 per cent, a second dose is given and the level again determined in twenty-four hours. Most patients with good hepatic function will show a normal or nearly normal level at this time. Patients who fail to respond normally are then given vitamin K preparations orally, with occasional supplementary intravenous doses. Three patients with severe jaundice failed to show the usual response, and the similarity of their prothrombin studies combined with the severe hepatic damage in the 2 studied post mortem suggests that silent jaundice definitely influences the procedure. Patients who do not show a fairly prompt prothrombin response to vitamin K therapy should not be subjected to operation until the proper response occurs. Some patients will never show this response and will die, but they will have been spared the expense and distress of a major surgical procedure. Others, who otherwise may have died, may recover under medical management.

Effects of Oxygen Lack on Cardiovascular System.—Graybiel states that the symptoms and associated changes in circulatory dynamics which may appear in the person with a normal heart under conditions of civil or military aviation are not indicative of heart failure but merely adjustments or compensatory reactions to oxygen deficiency. The normal heart is not damaged, but anoxemia can precipitate heart failure in patients with heart disease. Pain of cardiac origin and specific symptoms of heart failure (dyspnea, weakness and collapse) have been encountered occasionally. Congestion of the lungs has been observed occasionally and arrhythmias rarely. The experience of a number of investigators with patients with coronary disease and angina pectoris shows that exposure to low oxygen tensions does not produce pain in patients who do not suffer from angina pectoris, even though coronary disease and healed myocardial infarction are present. The author's experience with 4 patients with severe coronary disease and angina pectoris subjected to a simulated altitude of 14,500 feet for forty-five minutes confirms this view. To determine the incidence of serious cardiac illness or death among passengers the author analyzed the information from five major commercial airlines, which have carried more than seven million passengers; approximately one and one quarter million passengers were carried by planes which rarely flew higher than 10,000 feet,

and the remaining passengers were carried by planes which at times flew between 10,000 and 15,000 feet and occasionally even higher. Only 3 deaths, ascribed to heart failure, occurred aloft. Death occurred in 5 passengers shortly after deplaning, in 2 of them from heart failure. Deaths of passengers taking place shortly after deplaning must be few, because otherwise the airline insurance departments would be involved. There is a record of 4 passengers in whom angina pectoris developed and was controlled with oxygen and amyl nitrite and of 1 suffering from coronary occlusion at an altitude of 18,000 feet who recovered without additional oxygen. According to Colonel Tuttle, of the United Air Lines, during three years oxygen was given to 1,415 of 1,084,190 passengers on the advice of their physicians or because of "evidence of anoxemia" at some time during the flight. Persons with well compensated heart disease need not hesitate to fly at the highest altitudes now flown in commercial aviation, provided additional oxygen is used, but persons with severe valvular disease, easily provoked angina pectoris or recent congestive failure and the old and feeble should be advised against traveling by air.

Endometrioma of Ureter.—Randall states that a careful review of the literature failed to reveal a case of intraureteral endometrioma. He thinks that heretofore such growths have masqueraded as primary ureteral neoplasms. He reports such a case in the hope that such an eventuality will be thought of and that when it is recognized radical surgical intervention will be avoided. He points out that the cyclic occurrence of intensified symptoms, especially hematuria, in a woman in her fourth decade should always arouse suspicion. Such patients should always be examined for the possible presence of pelvic endometriosis.

War Medicine, with Special Emphasis on Use of Blood Substitutes. C. A. Janeway, Boston.—p. 371.

Chlorosis.—Olef believes that one of the factors responsible for the apparent rarity of chlorosis is the allocation of many mild and some severe cases into the categories of nutritional or microcytic anemia with achlorhydria. Chlorosis is probably not as rare as is implied. During the last four years he has encountered 8 such patients who presented no clinical or laboratory evidence of acute, recurrent or chronic infections, severe visceral disease or abnormal blood loss. The anemia in chlorosis is of the hypochromic microcytic type; and, since histamine anacidity or hypoacidity is a common observation, it is probably a deficiency disease conditioned by a gastrointestinal disorder. In chlorosis, the erythrocytes are hypochromic, small and flattened. Quantitatively the thrombocytes are normal or increased. In other types of anemia the platelets are reduced and rise with improvement of the anemia, but in chlorosis there is an inverse relation between the platelet level (when elevated above normal) and the hemoglobin value. When thrombocytosis is at

all present, it is well defined. Iron therapy cures the disease. The author suggests that the term "chlorosis" be discarded and that the disease should be more appropriately called "hypochromic iron-deficiency anemia of adolescence, frequently associated with achlorhydria."

Diabetes Mellitus. E. P. Joslin, H. F. Root and C. C. Bailey, Boston.—p. 416.

Poliomyelitis in Pregnancy.—Aycock points out that seasonal, climatic, familial and constitutional selectivities in the distribution of paralytic poliomyelitis among those exposed to the virus suggest differences in the persons exposed rather than to differences in exposure. Bulbar poliomyelitis following tonsillectomy and adenoidectomy suggests the mucosa of the upper part of the respiratory tract as the susceptible port of entry. The author cites 56 cases of poliomyelitis associated with pregnancy; 28 are from the literature and 28 from personal records. When the disease occurred during the pregnancy of 2 is not known, in 9 it occurred in the first, in 19 in the second and in 23 in the third trimester. Three cases occurred after delivery. Thus the latter months of pregnancy predominate, although the data for the first months may be discrepant. Collection data preclude statistical analysis, but it is estimated that the chance coincidence of the two conditions is roughly 1:1,000 cases of poliomyelitis and 1:50,000 pregnancies. In the Detroit outbreak in 1939, the estimated expectancy of coincidence of poliomyelitis in pregnancy was less than 1 case; 4 cases were observed. The suspected association with pregnancy, in view of accompanying alterations in mucous membrane due to estrogenic changes, suggests that autarcologic susceptibility to poliomyelitis may reside in the economy of estrogenic substance. To establish the frequency of poliomyelitis in pregnancy similar studies must be made in other outbreaks.

Roentgen Therapy in Lymphadenitis.—Hauser treated 108 consecutive cases of tuberculous cervical lymphadenitis with roentgen irradiation. The following physical factors were used: The kilovolt potential was 200, with 0.75 mm. of copper and 2 mm. of aluminum filtration, a target-skin distance of 50 cm., a fractional dose of 150 r every ten days for a period of one hundred days, or a total dose of 1,500 r. If 20 milliamperes of current is used, the output amounts to 35 r per minute. When the lesions are bilateral, 100 r is applied to each side of the neck at the same sitting. The time-intensity factor precludes any possibility of cutaneous damage even if

the treatments were to be repeated. In only 1 of the author's patients did atrophy and telangiectasis develop after four courses of treatment during two and a half years. Regardless of the rate of response, a total of ten treatments was given. Of the 108 patients 14 were excluded because they received only one or at most two treatments. Of the 94 remaining patients 67 per cent received a course of ten exposures. A satisfactory follow-up observation lasting from a few months to seven years was had for 87; 7 have been lost track of. Of the 87 patients 77 (88.5 per cent) had satisfactory results and 10 (11.5 per cent) were considered unsuccessfully treated. Results were considered satisfactory when lesions regressed from 50 to 100 per cent either during the course of treatment or within a few months after the last exposure, when symptoms (pain, tenderness or draining sinuses) were relieved and when the deformity disappeared or was negligible. All other results were considered unsatisfactory.

Amphetamine Sulfate in Obesity.—Chrisman and Maury selected 27 obese patients for treatment with amphetamine sulfate; all but 1 were women, 21 of whom were being treated for various gynecologic disorders and the others for "uncomplicated" obesity. All had previously but unsuccessfully attempted weight reduction through diet. Thyroid had been given to 11; in 9 it had failed to cause weight loss, and 1 of the 2 in whom it was effective was sensitive to it. The original dose of amphetamine sulfate was 5 mg. a day, 25 mg. being

given fifteen to thirty minutes before breakfast and before lunch. The dose was increased by 2.5 mg. every fourth day, but it never exceeded 20 mg. Other medication was given when indicated, but only 1 patient was also given thyroid. Dietary restriction was not imposed. The weight loss during amphetamine therapy ranged from 0 to 30 pounds (13.6 Kg.), with an average of 14 pounds (6.3 Kg.). The average rate was 2 pounds (1 Kg.) per week. The greatest loss, as well as the greatest inhibition of appetite, usually occurred between the second and fifth weeks. Fat disappeared chiefly from the abdomen and hips. Most patients lost their desire to "nibble" or overeat. There were only two failures. These occurred in uncooperative patients who suffered from nausea attributed to the medication, but it persisted after the drug was withdrawn. Other than the curtailment of appetite, the effect most frequently reported was a sense of well-being and increased energy. In a few instances dysmenorrhea was relieved. The weight of most patients remained fairly stationary on a maintenance diet after medication was discontinued. Placebos were given to 5 patients at the conclusion of treatment with amphetamine sulfate; 4 gained from 1½ to 6 pounds (0.7 to 2.7 Kg.) in five weeks, and 1 lost ¾ pound (0.3 Kg.). The drug, chiefly by virtue of its central action, appears to be a valuable aid in weight reduction.

Spirochetal Jaundice in Virginia.—Reid and Holt report 4 cases of Weil's disease, bringing the total for Virginia up to 13. As the leptospira of the disease is more difficult to isolate and cultivate than most other pathogenic organisms, specialized laboratory procedures are essential for an accurate diagnosis. The authors emphasize the value of the leptospiral agglutination-lysis test. One of their patients was a bricklayer, 1 a pump operator and 2 picked chickens in a market. The living quarters of the 4 patients were such that rat-borne infections were possible but not probable.

Tuberculosis in New York State.—According to Plunkett, to avert the possibility of introducing tuberculosis into the Army and to avoid the financial burden on the community that such an introduction would create, the following routine is

carried out in three New York state induction stations: Immediately after registration and before the physical examination is begun the selectee is sent to the roentgen ray department, an exposure of his chest is made and the film is developed and interpreted as soon as ready. A report of the interpretation is then submitted, usually before the medical examination is completed, to the medical officer in charge. If it is advisable to make another exposure the selectee is returned to the roentgen ray department before the record of his physical examination is completed. Another exposure is rarely necessary when the 14 by 17 inch (35.5 by 43.1 cm.) paper or 14 by 17 inch celluloid film is used, and when the 4 by 5 inch (10.1 by 12.7 cm.) film was used it was necessary for less than 5 per cent of the selectees at the Buffalo induction station. The following criteria are used in classifying the roentgen data for acceptance or disqualification of the selectees: (1) Chest normal includes all thoracic roentgenograms with no evidence of tuberculous infection, (2) chest normal includes roentgenograms indicative of a residual childhood infection, (3) chest positive embraces all thoracic roentgenograms showing evidence of the reinfection type of pulmonary tuberculosis and primary tuberculosis and (4) thoracic pathologic conditions needing clinical appraisal. The total number of men examined roentgenographically at the induction stations of Buffalo, Syracuse and Albany from Nov. 25, 1940 to March 14, 1941 was 14,923, and 127, or 0.9 per cent, of them were disqualified for military service because of roentgen evidence of tuberculosis and 21 men were disqualified because of thoracic pathologic conditions other than tuberculosis. Experience with the different available mediums for thoracic roentgenograms has led to the conclusion that until some cheaper and equally accurate method is developed the 4 by 5 inch roentgen photographic film is the most economical and most practical film for screening large groups of persons. Admission to the Army of men with active or potentially active tuberculosis represents a serious hazard to public health.

Diphtheria.—Nelson points out that for diphtheria antitoxin to be highly effective it must combine with the available toxin rapidly, and it must combine in firm bondage. An antiserum that exercises both of these qualities was first called an avid antitoxin by Kraus and Baecher in 1913. O'Meara stated that in Dublin, Ireland, the gravis type of organism, causing a hypertoxic diphtheria, is extremely prevalent and can be isolated from about 85 per cent of patients admitted to the Cork Street Fever Hospital, among whom the fatality rate is high despite early administration of maximal doses of the antitoxin now generally used. Antitoxin treatment of this hypertoxic diphtheria, it is pointed out, can meet with success only when the antitoxin available neutralizes without delay the all important substance B in the local lesion, halting its toxic onslaught, and when union between toxin and antitoxin is so firm that no dissociation follows the dilution of the mixture in the circulation. Finally, the antitoxin must withstand the addition to it of quantities of toxin rich in substance B without forfeiting its avidity. However, antitoxins in general use today are of low avidity. As yet avid serum rich in anti B factor cannot be produced at will, though attempts are being made. Reports are awaited which will show whether the gravis types of *Corynebacterium diphtheriae*, prevalent in areas where hypertoxic diphtheria predominates, may be used for the preparation of toxoids and antitoxins better adapted to its more effective immunization and treatment. O'Meara believes that avid antitoxin contains a considerable amount of anti B and anti A antibody, and that therefore it is therapeutically efficient for hypertoxic diphtheria in which both substances A and B are active.

Gas Gangrene Infection.—Kropp and Smith studied the effect on the connective tissue and phagocytes of experimental gas gangrene in guinea pigs and also the effect of sulfanilamide on such infection. The animals were infected according to the method used and described by Reed and Orr. The toxin of *Clostridium welchi* rapidly attacked and destroyed subcutaneous connective tissue and the phagocytic cells present in the connective tissue. The organisms and toxin spread chiefly along connective tissue planes. The accumulation and phagocytic activity of leukocytes and other phagocytic cells at the wound were inhibited by the toxin of *Cl. welchi*. Sulfanilamide intro-

duced into the experimental gas gangrene wound partially overcame the inhibitory action of the infection on the migration of leukocytes and phagocytic cells of the connective tissue and the ability of histiocytes to phagocytose *Cl. welchi*.

Amphetamine and Fatigue.—Simonson and his co-workers determined the effect of amphetamine on fatigue of the central nervous system by measuring the fusion frequency of flicker. This method cannot be influenced by any voluntary effort. Sixty-two experiments were carried out with 6 subjects, twenty-four of them after the administration of 10 or 15 mg. of amphetamine. The fusion frequency was measured in the morning and late afternoon. The subjects performed their usual daily work (not manual). For the amphetamine experiments amphetamine sulfate was given before lunch. Some control experiments were performed with each subject with sodium bicarbonate. The fusion frequency of all subjects was definitely lower in all control experiments at the end of the working day. The decrease varied on different days, depending on the amount of work done and in general paralleling the subjective feeling of fatigue. In contrast to these data there was a slight increase of the fusion frequency in all experiments with amphetamine. None of the subjects felt tired on the days they had amphetamine. Thus the abolition of the sense of fatigue coincides with the increase of the excitability of at least the retinocortical system, as shown by the increase of the fusion frequency, and probably of the whole central nervous system. In 5 of the subjects 10 mg. of amphetamine sulfate produced no subjective effect other than abolition of fatigue. One subject felt fresh at the end of the working day but complained of drowsiness in the evening and sleeplessness in the night. It was not possible to repeat the experiment with a smaller dose. All absolute values of fusion frequency were higher in the afternoon on the days when amphetamine was used than they were on control days. The increase of fusion frequency after amphetamine had been taken did not depend on the absolute value of the fusion frequency in the morning. Therefore it seems that amphetamine increases the excitability of the central nervous system independently of its state of fatigue and excitability at the time when amphetamine is given.

Electrocardiography.—Wood and his colleagues discuss the probable value of electrocardiography in military medicine, based on the data of the electrocardiograms of 705 unselected students, 153 students with definite or suspected heart disease (whose age corresponds to that of army recruits) and 229 unselected corporation executives (whose age corresponds to that of army officers). The authors' conclusions are: In persons less than 30 electrocardiography does not demonstrate cardiac abnormalities of importance from the military standpoint which are not discoverable on physical examination. In young persons in whom heart disease is present or is suspected electrocardiography rarely adds further significant information. Finally, electrocardiography may confuse the issue by revealing minor abnormalities in persons who have no cardiac lesion of military significance. In persons more than 30 and especially in those more than 40 electrocardiography may occasionally demonstrate degenerative heart disease while the physical symptoms or signs are still not definite. In the latter age group study of a person with cardiac pain or with cardiac arrhythmia is incomplete without an electrocardiographic tracing. However, even in these older persons the electrocardiogram may confuse the issue more often than it clarifies it unless the examiner is aware of the frequent occurrence and relative insignificance of certain questionable electrocardiographic abnormalities and unless he has a clear conception of the characteristics of definitely abnormal electrocardiographic patterns.

*Reduction of Hospital Infection of Wounds: Controlled Experiment. W. McKissock, Joyce Wright and A. A. Miles.—p. 375.

Reduction of Hospital Infection of Wounds.—According to McKissock and his collaborators, during a preliminary observation of four months the incidence of hospital infection with *Streptococcus pyogenes* among head wounds in a neuro-surgical unit was 10, or 31.3 per cent, in 32 air raid casualties, and 2, or 4.4 per cent, in 46 "clean" operative cases. After an improved dressing technic and a partially revised general ward procedure were instituted the incidence of hospital infection with *Str. pyogenes* was 1, or 2.2 per cent, in 46 air raid casualties and zero in 49 "clean" operative cases. The dressing technic was designed on the assumption that the main cause of hospital infection is the carriage of infected discharge from the wounds of 1 patient to the wounds of another patient by members of the medical and nursing staff. Air contamination and droplet infection was considered less important. With the addition of bins for dirty dressings with foot action lids the dressing team can be reduced to a minimum of three: The dresser who begins his work when the bandage and outer dressings have been removed from the wound and is assisted by the "dirty nurse." He applies the new bandage after which he washes his hands and forearms. The "clean nurse" looks after the trolley and its contents only, touching nothing throughout the entire dressing round. The "dirty nurse" removes the outer dressings and stands by until she assists in applying the final new bandage, after which she washes her hands and forearms. The bin porter takes care of two bins (one for washable soiled dressings and the other for dressings which must be destroyed). He washes his hands and forearms only at the beginning and the end of a round of dressings. All ward cleaning and bed-making were finished half an hour before dressings were started. No more than one dressing was uncovered at one time. No person having an infected lesion of the hand or a sneezing cold was permitted to dress wounds.

Liver Extract for Tropical Macrocytic Anemia.—

Trowell found a crude liver extract (from British drug houses) to be satisfactory in the treatment of 2 patients with uncomplicated tropical macrocytic anemia. The weekly dose of this extract varied from 5 to 10 cc. The author believes that this less expensive crude liver extract may prove more effective in the treatment of macrocytic anemia than the refined liver extracts which are potent in the treatment of pernicious anemia. He suggests that some fractions essential to the cure of tropical macrocytic anemia may be lost in the refining process.

Blood Amino Acids in Hematemesis.—Black determined the amount of amino acid nitrogen in the blood of 7 patients with azotemia secondary to gastroduodenal hemorrhage. The data show an increase in amino acid nitrogen at the time of bleeding, the average being 15.2 mg. per hundred cubic centimeters. This increase is especially striking in view of the anemia which most of the patients had, since the amino acid content of plasma is only about a fifth of that of the erythrocytes, and low amino acid values might have been expected. The amino acid nitrogen level fell gradually as recovery took place. While a general correspondence existed between urea and amino acid values, the blood urea level was not necessarily highest at the same time as the amino acid nitrogen level. The increase in amino acid nitrogen probably indicates hepatic dysfunction, though this is slight compared with the renal impairment. This disparity may be due to the greater importance of circulatory factors in renal function.

Anginal Symptoms Arising from Hypothyroidism.—Zondek suggests that the possibility of hypothyroidism be kept in mind when patients with anginal symptoms are being treated. There are a number whose condition can be related to hypothyroidism. The main signs are a tendency to cardiac dilatation (mostly in the form of a pointed, sometimes rounded, dilatation of the left ventricle), bradycardia and low blood pressure. The electrocardiogram often shows flattening of the P and T waves, and the T wave is sometimes negative. The PR interval is sometimes prolonged. These patients complain of pain or substernal distress and compression or sometimes only of troublesome precordial tightness. They often find it difficult to describe clearly what they feel. The sensations are more or less continuous, whereas true anginal attacks are rare. As in true myxedema, an increase in blood cholesterol is an early symptom. The capillaries appear constricted and reduced in number, and the circulation in them is slow. Usually small doses of thyroid (0.5 to 0.7 Gm. weekly) are effective. Treatment should be continued for several weeks with short interruptions and repeated when bradycardia reappears. The cardiovascular syndrome described may be designated abortive myxedematous heart. Unlike the symptoms of ordinary vagal heart (primary vagotonia) its symptoms and signs are little, if at all, affected by drugs that decrease the vagal tonus or cause vasodilatation.

Coronary Calcification and Thrombosis in Infant.—

Coronary thrombosis and calcification in young children raise the following questions. 1. Is there a relation between disease, intoxication or constitutional anomaly in the mother and the occurrence of arterial calcification and thrombosis in the infant? 2. Do these vascular changes help explain disturbances in respiration and circulation in cases of sudden death immediately or shortly after birth? Van Creveld discusses these questions in connection with the case of a girl aged 6 weeks who died during an attack of severe dyspnea five days after admission to the hospital. Necropsy disclosed coronary calcification and thrombosis. There was a peculiar swelling and necrosis of the capillary endothelium of the renal glomeruli. The child's mother had had bronchial asthma for some years, and during pregnancy she had made use of a prescription containing among other substances caffeine and lobeline. The hypothesis is advanced that the coronary lesions in the child were related to the allergic mother's use of drugs, giving rise to a localized hyperergic reaction.

Influenzal Meningitis.—Nathhorst reports data on 15 cases of influenzal meningitis observed at the children's hospital in Göteborg during the years from 1934 to 1940. During this period 118 cases of purulent meningitis were observed; cases of the influenzal (Pfeiffer's) form amounted to 11.8 per cent. The ages of the patients varied from 4 months to 10 years, but 11 were less than 2 years old. The author gives particular attention to the cases in which sulfanilamide or sulfapyridine was used. Specific serum therapy was not employed, although some patients were given serum (without complement) in small doses. Sulfapyridine was given in full doses to 6 children. The 2 oldest (aged 8 and 10 years) recovered. Of the children not treated with sulfapyridine only 1 was cured (aged 3½ years). With 1 exception, all the children who died were less than 2 years old. It seems that age is of greatest importance for the prognosis. Since the action of sulfapyridine is rather uncertain in influenzal meningitis, the author recommends that specific serotherapy be given in addition to it.

Threatening and Recurrent Abortion.—Wenner presents observations on 133 cases of threatening and habitual abortion that were observed at the Basel clinic from 1930 to 1939. Until 1936 the treatment was purely conservative, that is, it was limited to bed rest and sedatives; after 1936, however, corpus luteum therapy was used. In a few cases vitamin E was given in addition to the corpus luteum. Comparison of the therapeutic results reveals that those of conservative treatment are inferior to those obtained with corpus luteum. In evaluating the efficacy of the corpus luteum therapy, it must be considered that at first the doses were rather small; thus some of the failure of this therapy must doubtless be ascribed to insufficient dosage. From results obtained in recent years with adequate doses of corpus luteum the author concludes that it should never be dispensed with in the treatment of threatening or recurrent abortion. In cases of the latter condition therapy should be begun early, that

is between the sixth and eighth week of pregnancy. Ten mg. of a corpus luteum preparation should be given every week by intramuscular injection, either 5 mg. given twice or 2 mg. given five times. If oral medication is preferred the dose must be from six to eight times as large. Because abortion is most likely at the time menstruation is due, bed rest is advised, and large doses are administered daily at these times. From the fifth to the seventh month of pregnancy the weekly dose is decreased to 2 mg. given twice a week by intramuscular injection. If abortion threatens in spite of this treatment, larger doses should be administered and the patients should remain in bed until the symptoms have subsided.

- *Results of Splenectomy in Erythroblastic Anemia: Two Cases. M. Acuña.—p. 126.

Splenectomy for Erythroblastic Anemia.—Acuña observed 2 patients with erythroblastic anemia who had splenectomy performed. The operation was done when the patients were aged 10 months and 5 years; they lived up to the ages of 9 and 15 years, respectively. The immediate results of splenectomy were good. The crisis of the blood and the general condition improved, the appetite and weight increased and the complexion, the color of the skin and the aspect of the mucosa also improved. The good results lasted for one or two years, after which erythroblastic anemia reappeared and progressed slowly but constantly. The physical development of the patients was deficient, and puberty was retarded. The patients grew, for the few years they lived, with progressive anemia, osteoporosis and a feeble constitution.

Treatment of Epidemic Meningitis.—Mark reports observations on 117 patients with epidemic meningitis, of whom 48 were treated with acetylsulfanilamide, 39 with sulfapyridine and 30 only with serum and spinal puncture. The mortality was 8.4, 7.7 and 53.5 per cent respectively. The fact that of the group of 30 treated with serum and puncture but without a sulfanilamide preparation 16, or more than half, died demonstrates that sulfanilamide and its derivatives have greatly decreased the mortality of epidemic meningitis. Sulfapyridine was administered by mouth, whereas acetylsulfanilamide was given intravenously, intraspinally and by mouth. Acetylsulfanilamide in a dose of 5 cc. of a 30 per cent solution was given intraspinally at the time of the diagnostic puncture. In addition two or three intravenous injections of 5 cc. each were given daily for five or six days. The intraspinal administration may be repeated on the second day. After the intravenous treatment acetylsulfanilamide therapy is continued orally for four to seven days (two tablets three times daily). In this form acetylsulfanilamide proved more effective than did sulfapyridine. There was not a single death among 13 patients in whom early intraspinal administration of acetylsulfanilamide was employed. There were no harmful after-effects. Determination of the

comparative efficacy of acetylsulfanilamide and sulfapyridine would necessitate alternate application of the two preparations on a large number of patients. Either preparation should be employed in every case of epidemic meningitis.

Autotransfusion in Prophylaxis of Apoplexy.—Kühn directs attention to the treatment of cerebral hemorrhage that was recommended by Colella and Pizzillo in 1934. These authors took 25 or 30 cc. of blood from a brachial vein, mixed it with a small amount of sodium citrate solution and injected it into the gluteal muscle. Autotransfusion had a hemostatic effect and proved helpful in cerebral hemorrhages and their sequels irrespective of their cause or nature. Kühn resorted to autotransfusion for 250 patients, whom he classifies into four groups. The 81 patients of the first group had had an apoplectic attack and a threatened relapse because of increased intracranial pressure. Autotransfusion reduced the incidence of recurrence as well as of death. The author employed it in the presence of increased intracranial pressure either with or without hypertension. In a second group of 3 patients the apoplexy was in the early stage. Autotransfusion was followed by great improvement. The third group comprising 110 patients includes those in whom unilateral paresthesias, vertigo, temporary motor pareses, unilateral tremor, abnormal sensations of heat and cold and temporary aphasic and visual disturbances indicates considerable organic changes and the threat of apoplexy. In nearly all these patients improvement was noticeable after autotransfusion, and apoplexy was prevented. A fourth group of 56 patients had dull pain in the occiput or forehead, vertigo, loss of memory, a feeling of congestion in the head, vascular crises and tinnitus aurium. In this group also autotransfusion was followed by improvement.

Cerebral Concussion and Contusion.—Jaeger argues that differentiation between cerebral concussion, contusion and compression is difficult and that it is advisable to classify all cranio-cerebral injuries into those requiring conservative treatment and those necessitating surgical intervention. Conservative treatment should be employed in simple cerebral concussion, in cases complicated by edema of the brain and in contusion. Symptoms of concussion are most severe immediately after the trauma and subside in several hours or days without leaving anatomic changes. If headache, vertigo and vomiting persist after the unconsciousness has subsided or if a single nerve is paralyzed or hemiplegia exists, edema is to be suspected. This necessitates repeated spinal punctures and dehydration of the brain by means of intravenous injection of a 50 per cent solution of dextrose. Contusion is characterized by prolonged loss of consciousness, which may be so severe that incontinence of all the sphincters results and that all reflexes become abolished. As the unconsciousness subsides, there is usually disorientation and occasionally motor unrest, nausea and vomiting. Paralytic symptoms exist, the intracranial pressure is always increased and the cerebrospinal fluid contains blood. If the symptoms increase, danger threatens. It is essential to make careful neurologic and roentgenologic examinations and to keep pulse rate, blood pressure and respiration under constant control. Exploratory trepanation may be necessary in doubtful cases, if no improvement is observable after several days of conservative treatment. Exploratory trepanation is the only means of differentiating contusion from cerebral hemorrhage. Large accumulations of blood under the dura should be removed.

Blood Picture in Sporadic Grip.—Uncomplicated sporadic grip, according to Korovin, differs from the epidemic variety by a lesser contagiousness, the presence of chilling, the predominance of symptoms referable to the upper respiratory tract, the absence of severe prostration in the presence of a high

temperature, frequent herpetic eruption and a favorable course. In 53 per cent of the cases of sporadic grip there was leukopenia, in 35 per cent a normal leukocyte count and in 12 per cent leukocytosis. Neutropenia was present between the second and the fifth day of the illness in the cases of uncomplicated grip, with leukopenia or a normal leukocyte count. Lymphopenia was present during the first two to three days and eosinopenia during the entire febrile period. The number of monocytes was either normal or slightly diminished. In cases of sporadic grip leukopenia is not as frequent as in cases of epidemic grip. Toxic and degenerative alterations of the neutrophils are less common and less pronounced. The essential difference, however, in the blood pictures produced by the two forms is the absence of monocytosis or of histiocytosis in the sporadic form. The latter is characteristic of epidemic grip. In cases of complicated sporadic grip the majority of the patients had neutrophil leukocytosis. Epidemic and sporadic grip are distinct disease entities which may be differentiated clinically, epidemiologically and in part on the basis of the blood picture. Isolated cases of the epidemic variety of grip are to be seen during an epidemic-free interval. The patients probably act as reservoirs of the epidemic virus.

Morphologic Development of Bone Marrow in Fetus. N. G. Nordensson.—p. 2283.

Tendovaginitis Treated with Roentgen Irradiation and Immobilization.—Bertelsen states that freedom from symptoms resulted after an average of twenty-four days' treatment with combined roentgen radiation and immobilization in 83 cases of acute tendovaginitis or peritendinitis crepitans in which the treatment was begun from one to fourteen days after the onset of the disorder, in an average of thirty-two days in 19 cases of acute disease in which the treatment was started after two to six weeks, in an average of forty-two days in 15 cases of subacute disease in which treatment was given from one and a half to three months after the onset (1 case of subacute disease with particularly protracted course in which the treatment lasted eight months being excluded), in an average of forty-six days in 14 cases of subchronic disease in which admission took place after three to twelve months' duration of the disease and in an average of sixty days in 13 cases of chronic disease in which treatment was given after more than a year's duration of the disease, the time here varying greatly in the individual cases. The ability to work was restored after an average of five weeks in the cases of acute disease, after two to two and a half months in the cases of subacute and subchronic disease and as a rule after a still longer time in the cases of chronic disease. The author says that the frequency of recurrence and of chronic tendovaginitis or peritendinitis crepitans depends largely on the time of institution of the combined roentgen and immobilization treatment. Examination of 104 patients from one to ten years after treatment did not show recurrence, chronic tendovaginitis or peritendinitis in the 52 cases in which the treatment was begun during the first two weeks after the onset of the disease. The disorder became chronic in 1 of 15 patients with acute disease treated after two to six weeks, in 1 of 12 with subacute disease treated after one and a half to three months, in 5 of 15 treated after three to twelve months and in 4 of 13 treated after more than a year's time, and the conditions with regard to recurrence were similar.

Book Notices

Trauma and Disease. Edited by Leopold Brahdy, B.S., M.D., Physician in Charge of Occupational Diseases and Injuries in the Office of the Corporation Counsel of the City of New York, and Samuel Kahn, B.S., M.D., Medical Examiner in the Bureau of Workmen's Compensation of the Department of Labor, State of New York. Second edition. Cloth. Price, \$7.50. Pp. 653, with 13 illustrations. Philadelphia: Lea & Febiger, 1941.

This volume includes eighteen chapters devoted to the relation of trauma to specific disease conditions, written by authors prominent in their respective fields. The first chapter, by Drs. Brahdy and Kahn, the editors, serves as an introduction to the general subject and presents fundamental principles for determining the relationship between trauma and disease.

The articles are written from the point of view of the medical expert; as indicated in the opening chapters, an attempt has been made to avoid introducing a predominant medicolegal influence. Certainly this book is "must" reading for any one going to court as a medical expert, a witness, or a lawyer in a case involving trauma and disease. It should be of great value to those interested in industrial medical problems, compensation commissions and the many physicians, lawyers and jurists who are called on to decide in given cases what the effects of trauma may be. Particularly noteworthy are the chapters on trauma and heart disease, by Drs. Paul D. White and R. Earle Glendy, on trauma and neoplasms, by Dr. Leila Charlton Knox and on trauma and mental disorders, by Drs. Franklin G. Ebaugh and John D. Benjamin. The chapter on trauma and diabetes mellitus is, appropriately enough, bound upside down in the volume reviewed, beginning on page 545 and ending on page 560. The chapter presents the little that is known on the relationship of trauma to the etiology of diabetes and it is apparent that this is appallingly little. To make up for this the chapter is rounded out or padded with miscellaneous information on the disease that belongs more properly in a textbook on diabetes. For instance, sections are devoted to obesity, lack of exercise, the glycosuria deficiencies and diagnosis, errors in the interpretation and performance of blood sugar tests and diagnosis. Obviously, it could be argued that every important fact about diabetes is in some way related to trauma; but this is not a textbook of facts about diabetes.

Studies in Haemolytic Streptococcus Fibrinolysin, Antifibrinolysin and Antistreptolysin, with Particular Reference to Rheumatic Fever. By Sten Winblad. *Acta pathologica et microbiologica Scandinavica Supplementum XLIV.* Paper. Pp. 229, with 13 illustrations. Copenhagen: Ejnar Munksgaard, 1941.

This monograph contains a detailed and careful review of classification and antigenic properties of the streptococci, and numerous personal observations on fibrinolysin, antifibrinolysin and antistreptolysin. The work was carried out at the University of Lund, Sweden, from which other authors, connected with Dr. Winblad, have presented important contributions to the study of rheumatic fever. Therefore especial attention is directed to the significance of variations in titer of antifibrinolysin and antistreptolysin for the etiologic problem of rheumatic fever. In rheumatic fever the titer of both these antibodies rises to the level observed in other streptococcal diseases. The titer rises during the first weeks of the disease even if no accompanying or preceding streptococcal infection can be traced, and it slowly returns to normal, though it remains elevated longer than the sedimentation rate. In the interpretation of his data the author asks himself whether the occurrence of an elevated antibody titer against an organism justifies the opinion that the disease is due to that specific agent. The answer is obviously negative. He indicates that other evidence is necessary, such as "the direct isolation of the specific causative organism in the patient's blood, tissues, or excreta." The theory that rheumatic fever represents the allergic response of some individuals to streptococci might explain the difficulty encountered in the demonstration of the presence of this organism in the affected tissues. The author warns, however, that it must not be construed that the high antifibrinolysin and antistreptolysin titer implies the presence of an allergy to streptococci, because genuine allergy is shown only by the tissue reaction against the antigen, and not by the presence of humoral antibodies. Furthermore, the author observed that the rise of

antibody titer may occur either before or after the onset of the rheumatic attack. This last observation differs from the observations reported by some American authors and should be confirmed independently. The work presented here does not, and could not, arrive at a conclusion as to the probable etiology of rheumatic fever. It is the impression of the author that his findings agree with, but do not prove, the allergic streptococcus theory. The reviewer feels, however, that the same findings agree as well with the theory of a virus etiology in which the streptococcus plays the role of the most frequent, but not exclusive, activating or associated organism. The present monograph will be valuable to all those engaged in research in the etiology of rheumatic fever, because of the personal observations and because of the rich literature (three hundred and seventy references), including some not easily accessible important work by Scandinavian authors.

Das Schlichtbild der Lunge des Tracheobronchialbaums und des Kehlkopfes. Von Kurt Greinader, Dozent für Röntgenologie an der Universität Berlin. Cloth. Price, 37.30 marks. Pp. 230, with 509 illustrations. Leipzig: Georg Thieme, 1941.

This is an elaborate presentation of the subject of body section roentgenography as applied to the upper air passages. After a chapter setting forth in adequate detail with text and geometric drawings the theory of laminagraphy, also sometimes called planigraphy or tomography, the author proceeds to the discussion of technic as applied to the lungs, the findings in the normal lung, bronchial diseases, nonspecific inflammatory diseases of the lung, lung abscess, differential diagnosis of lung abscess and empyema, foreign bodies, and a long chapter of more than forty pages on lung tumors and bronchial obstructions. Tuberculosis and pneumoconiosis are assigned about seventy-five pages. The remainder of the book is devoted to the trachea and to the larynx.

The illustrations are especially numerous and serve admirably to illustrate the author's contention that there are many lesions of the lung in which tomographic demonstration is much more convincing than the single film and often shows up lesions which cannot be otherwise demonstrated on the x-ray film even when made stereoscopically.

The expense of an instrument especially planned for body section roentgenography is as yet prohibitive for private practice and for many hospitals and clinics, but a fairly efficient equipment can be attached to many of the existing types of radiographic tables which will give valuable help in a certain limited class of cases. In addition to the installation expense, one must consider the additional expense of multiple films necessary for the various sections to procure a film portraying the exact section needed for the study of the part, and also the fact that even in the section under study only a limited field, corresponding roughly to less than an 8 by 10 inch film, can be demonstrated with satisfactory detail.

Polarography: Polarographic Analysis and Voltammetry Amperometric Titrations. By I. M. Kolthoff, Professor and Head of Division of Analytical Chemistry, University of Minnesota, Minneapolis, and J. J. Lingane, Instructor in Chemistry, University of California, Berkeley. Cloth. Price, \$6. Pp. 510, with 141 illustrations. New York: Interscience Publishers, Inc., 1941.

Polarographic or voltammetric analysis was invented about twenty years ago by Jaroslav Heyrovsky, and its subsequent development is largely attributable to his efforts. Its use in analytic chemistry and other fields is due to the fact that when a solution of an electrolyte is electrolyzed in a cell consisting of a dropping mercury electrode and a nonpolarizable electrode it is possible to determine from the resulting current-voltage curve both the nature and the concentration of the reducible or oxidizable substance present. Thus it lends itself to the qualitative and quantitative determination of many inorganic and organic substances and radicals. About 400 journal articles have appeared on the subject of polarography, but this is the first monograph on this subject in English. The eight parts include an introduction, discussion of the many theoretical principles involved, apparatus, inorganic and organic analysis, biologic applications, use of platinum electrodes and amperometric titrations. The appendix includes a list of substances with their respective half-wave potentials in various electrolytes. This appendix is invaluable to any one who contemplates work with a polarograph. The bibliography, indexing and

illustrations are all excellent. This monograph makes available the theoretical and practical aspects of a subject which is rapidly becoming popular with analysts. Literature contributions are summarized and an attempt is made to explain discrepancies in reported results. It should be available in every laboratory possessing a polarograph and to every person interested in the subject.

Abdominal Surgery. By John E. Hammett, M.D., F.A.C.S., Professor of Surgery, The New York Polyclinic Medical School and Hospital, New York. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 356. New York, Toronto & London: Oxford University Press, 1941.

Thoracic Surgery. By Charles W. Lester, A.B., M.D., F.A.C.S., Assistant Clinical Professor of Surgery, New York University, New York. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 141. New York, Toronto & London: Oxford University Press, 1941.

Fractures and Dislocations. By Kenneth M. Lewis, B.S., M.D., F.A.C.S., Assistant Clinical Professor of Surgery, New York University College of Medicine, New York. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 217. New York, Toronto & London: Oxford University Press, 1941.

Histology and Embryology. By José F. Nonidez, Sc.D., Professor of Anatomy, Cornell University Medical College, N. Y. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 199. New York, Toronto & London: Oxford University Press, 1941.

Diseases of the Respiratory Tract. By Jacob Segal, M.D., F.A.C.P., F.A.C.C.P., Attending Physician, Riverside Hospital, New York. Foreword by Harry Wessler, M.D., Director of Medical Service, Bronx Hospital, New York. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 172. New York, Toronto & London: Oxford University Press, 1941.

Obstetrics. By Hervey Clock Williamson, M.D., F.A.C.S., Associate Clinical Professor of Obstetrics and Gynecology, Cornell University Medical College, New York, and George Schaefer, M.D., Assistant Attending Surgeon in Gynecology Clinic, St. Luke's Hospital, New York. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 113. New York, Toronto & London: Oxford University Press, 1941.

Surgery of Head and Neck. By Arthur S. McQuillan, A.B., M.D., F.A.C.S., Clinical Professor of Surgery, New York University Medical College, New York. Oxford Medical Outline Series. Cloth. Price, \$2. Pp. 138. New York, Toronto & London: Oxford University Press, 1941.

Each of the books in this series is in outline form. Each disease or condition is discussed under etiology, pathology, diagnosis, treatment and prognosis; this arrangement, of course, is not followed in the book on histology and embryology. Obviously the outline method has serious limitations and cannot be considered sufficiently detailed to serve as an adequate guide to diagnosis and treatment. It would seem that these books would have their greatest usefulness in assisting preparation for some of the various types of examinations with which physicians are so commonly confronted.

The Vitamin Content of Meat. By Harry A. Waisman, Ph.D., Research Associate in Biochemistry, University of Wisconsin, Madison, and C. A. Elvehjem, Ph.D., Professor of Biochemistry, University of Wisconsin, Boards. Price, \$3. Pp. 210. Minneapolis: Burgess Publishing Co., 1941.

The intensive research on the nutritive value of meat carried on at the University of Wisconsin during the past few years has logically culminated in the publication of this book, which combines the results of these original investigations with a comprehensive review of the literature. Dietitians will be interested in the tables giving the nutritive values of several cuts of meat and in the vitamin losses observed as the result of the cooking methods used in preparing these cuts for the table. The critical review of assay methods and comparison of the results obtained by various methods employed in vitamin assays will be valuable to those interested in determining the vitamin content of foodstuffs. Also of great value is the comprehensive bibliography on the chemistry, physiology, pathology, assay methods and therapeutics of the various vitamins.

A Manual of Bandaging, Strapping and Splinting. By Augustus Thorndike Jr., M.D., F.A.C.S., Associate in Surgery, Harvard Medical School, Boston. Paper. Price, \$1.50. Pp. 144, with 117 illustrations. Philadelphia: Lea & Febiger, 1941.

Although intended primarily for medical students, nurses and orderlies, this handy size paper covered volume is highly recommended to practicing physicians. The book follows the general course given in the department of surgery at Harvard Medical School to second year students. The author presents and describes the technic of the use of dressings, bandages, adhesive plaster and splinting material. In the foreword Elliot Cutler says that "surgeons, like musicians, take pride in their tools and in the performance of their tasks." The illustrations are

the meat of the manual and visualize to the beginner the steps which must be taken to let the young surgeon remember that a neat dressing often bespeaks a good job beneath. The student will soon learn that the principles of support and immobilization entail fundamental concepts in the proper care of injury and infection. Cutler says that especially is this book valuable because of the imminence of worldwide hostilities. The book contains descriptions and illustrations of the dry sterile dressings for clean wounds, septic wound dressings, the treatment for strains, sprains and contusions, dislocations and emergency splinting, the transportation of fracture cases, plaster of paris and similar bandages.

Surgical Diseases of the Spinal Cord, Membranes, and Nerve Roots: Symptoms, Diagnosis and Treatment. By Charles A. Elsberg, M.D., Consulting Surgeon, Mount Sinai Hospital, New York City. With Chapters by Cornelius G. Dyke, M.D., Associate Professor of Radiology, College of Physicians and Surgeons, Columbia University, and Abner Wolf, M.D., Assistant Professor of Neuropathology, College of Physicians and Surgeons, Columbia University. Cloth. Price, \$14. Pp. 598, with 249 illustrations. New York: Paul B. Hoeber, Inc., 1911.

In 1916 Elsberg wrote "Diseases of the Spinal Cord" and in 1925 "Tumors of the Spinal Cord." The present volume is a modern version of both his previous works. Elsberg has been a pioneer in neurologic surgery, particularly specializing in surgery of the spinal cord. From his initial endeavors much of our present surgical technic has arisen as well as considerable knowledge of diagnosis and localization. In this volume Dyke discusses the roentgenologic aspects and Wolf the pathology. The result is an authentic statement of the subject well documented and derived from seasoned experience. The book is beautifully written and well illustrated and should be in every neurologist's library.

The Elegant Eighties When Chicago Was Young. By Herma Clark. With a foreword by John T. McCutcheon. Cloth. Price, \$7.50. Pp. 258, with 36 illustrations. Chicago: A. C. McClurg & Co., 1941.

This book offers a fictitious correspondence between two women who lived in Chicago in the 1880's. That was a period in which medicine in Chicago had many interests. The chapters devoted to 1883 tell the story of Dr. Mary H. Thompson and the Women's and Children's Hospital, where Dr. Sarah Hackett Stevenson began her great career. One hears of the introduction of consumption cures and magnetic belts. The book is made interesting with wonderful reproductions of the personalities who were important in the Chicago of the 1880's. It is beautifully printed and is certain to be a delight to every one who has a taste for the qualities of the more quiet existence of the 1880's. Here too is the story of the founding of the Newberry Library, of the drama and particularly of the interesting society of that period.

Manual for Medical Records Librarians. By Edna K. Huffman, R.R.L., Director, School for Medical Records Librarians, Grant Hospital, Chicago. Cloth. Price, \$3. Pp. 308, with illustrations. Chicago: Physicians' Record Company, 1941.

In this manual, record librarians are given a brief history of medical records and an analysis of the use and value of the medical records and procedures in the medical records department such as organization and management, storage and cross indexing. Qualifications and training of the medical records librarian are discussed and certain of the so-called secondary duties of medical records librarians. There is little doubt that a book of this kind is needed, but it is the reviewer's belief that a considerable amount of obsolete material is included and that somewhat greater emphasis should be given toward the more modern methods and less space occupied in describing those procedures which can no longer be considered up to date.

An Introduction to Medical Science. By William Boyd, M.D., M.R.C.P., F.R.C.P., Professor of Pathology and Bacteriology in the University of Toronto, Toronto. Second edition. Cloth. Price, \$3.50. Pp. 258, with 124 illustrations. Philadelphia: Lea & Febiger, 1941.

This is a volume for orientation, planned primarily to explain to the nurse causes of disease and the bodily changes that occur. When one is able to survey the picture as a whole, individual sections become more clear. The style is simple, direct and understandable by any person of late high school or college education. The book may well be recommended to the general reader as well as to the nurse.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

WEIGHT REDUCTION

To the Editor:—In October 1938 in the *Journal of the Missouri Medical Association*, Werner and Weir published an article on the treatment of obesity in adults. They studied 77 patients; 76 were women, and 75 had obesity of the pituitary type. For the past three months I have been using their method on 6 patients who did not respond to diet alone. (Werner and Weir advocated a diet of about 1,500 calories, the giving of 1 cc. of solution of posterior pituitary intramuscularly twice a week and administration of desiccated thyroid, 1 grain [0.06 Gm.] three times a day.) My results have been surprisingly good. However, this is what is worrying me: Do you believe the patients will regain their former weight when the administration of solution of posterior pituitary is discontinued? Of course I intend keeping them on the low caloric diet.

M.D., New York.

ANSWER.—The article by Werner and Weir to which reference is made does not contain any evidence that the injection of 1 cc. of solution of posterior pituitary intramuscularly twice a week contributed toward the weight reduction of their patients. The use of solution of posterior pituitary by these authors was based merely on inference from the previous work of Raab; their simultaneous use of thyroid and low caloric diets may easily account for the losses of weight which occurred. It is, therefore, most probable that the discontinuation of the use of solution of posterior pituitary will make no difference, providing one continues with the rest of the treatment. However, if it is intended to discontinue the use of thyroid, it is likely that the patients will regain their former weight. For, since they did not respond to dietary treatment alone, it is apparent that they were not ingesting the prescribed diet and, therefore, are still eating sufficient food to maintain their high weight when the metabolic rate is not speeded up by thyroid.

This illustrates the fallacy of weight reduction by medication, unless the patient presents a type of obesity (such as the relatively rare, true hypothyroid obesity) for which thyroid may be prescribed and continued indefinitely. The essence of good treatment for a permanent result in the usual type of obesity is to teach the patient a new and better food habit to replace the previous faulty food habit.

STERILIZATION AND CARE OF HYPODERMIC EQUIPMENT

To the Editor:—How long will rustless needles (for injection purposes) remain sterile without rusting (1) if left in a Castle sterilizer with its lid down for one week or longer, (2) if removed from the sterilizer after boiling for several minutes and then placed in a sterile towel, or (3) if the syringe and rustless needles are wrapped in a dry towel, placed in the sterilizer for sterilization and then removed and allowed to dry and cool? When a physician is called to see a patient, usually in the middle of the night, who is suffering from, say, cardiac asthma, bronchial asthma or severe pain requiring a hypodermic injection of some drug, it is necessary to have a member of the family hunt for a suitable pan or vessel and then to boil the syringe and needle, fill it with water, allow it to come to the boiling point, boil the syringe and needle for five minutes (at least) and then wait another five minutes for the water to cool before removing them from the pan. These procedures will usually require between fifteen and twenty minutes and perhaps longer. Considerable time is accordingly wasted waiting for the syringe and hypodermic needle to be sterilized and ready for the administration of the injection. The question now is How can the syringe and needle be sterilized and kept sterile in order to be ready for instant use when required, whether in one week or several weeks subsequent to their sterilization?

E. L. Hergert, M.D., Brooklyn.

ANSWER.—Any object which is actually sterilized and so wrapped that it is protected against contamination will remain sterile forever. However, the procedures mentioned in the inquiry are not recommended. The Castle sterilizer does not employ steam under pressure. Boiling water or steam at atmospheric pressure may not sterilize in less than thirty minutes. Either of the following methods should be considered:

(a) With needle attached and plunger removed, wrap the syringe in cotton cloth so that it is completely covered by several layers. Place the wrapped syringes on a wire rack at least 2 inches above the water level in a household pressure cooker. Sterilize at 15 pounds steam pressure for twenty to thirty minutes. Turn off the heat and allow the steam pressure to go down. When the pressure is down nearly to zero, open the valve, allow any remaining steam to escape and then open the cooker. The wrapped syringes will be found slightly moist.

Place them in a kitchen gas or electric stove oven at moderate heat; they should be dry within five minutes. (A pressure cooker is actually a small autoclave, and small sizes may be bought from kitchenware furnishers for \$10 or less.)

(b) Many modern gas or electric kitchen stoves have well insulated ovens with thermostatic control. If time allows, there is no better way of sterilizing clean glassware than by dry heat. Glassware is also etched less readily by repeated exposure to dry heat than by steam. Wrap the syringes in cloth as described. Bake them in the oven at about 160 C. (320 F.) for at least two hours.

When wrapped syringes are sterilized by either of these methods, they may be protected from dust and handling by placing them in small paper bags. If they are dry they will remain sterile indefinitely and the needles will not rust, although it is advisable to use "rustless" needles.

DESENSITIZATION TO HORSE DANDER

To the Editor:—A youth aged 18 has had bronchial asthma since he was an infant. It has been necessary for him to live in Tucson, Ariz., the year round until last summer, which he spent here, because all methods of treatment in Memphis have failed to relieve his asthma while in this city. He attends the state university in Tucson and has been told that they will not admit him for the coming season unless he takes injections of "horse dander" to "immunize" him from this substance, to which he is extremely sensitive. The patient requests that I start these injections. It is my opinion that this would be extremely dangerous because of the severe attacks of asthma which he has had. I would appreciate an opinion regarding the proper procedure in such a case.

M.D., Tennessee.

ANSWER.—Immunization against horse dander is a routine procedure and is practiced by almost all men who devote special attention to the subject of allergy. There is little danger to the patient, provided suitable precautions are observed.

A scratch test to horse dander should be done first and, if a pseudopod forms (indicating a four plus reaction), the patient is given on another day a series of intradermal tests with weak dilutions including 1:100,000, 1:1,000,000, 1:10,000,000 and 1:100,000,000 with a control. Desensitization should then begin with that dilution which just fails to give a positive reaction. For example, if the reaction to the 1:1,000,000 dilution is 2 plus and the 1:10,000,000 reaction is negative, start the treatment with 0.10 cc. of the 1:10,000,000 extract. Then the patient should receive 0.15 cc., 0.22 cc., 0.30 cc., 0.45 cc., 0.65 cc. and 0.85 cc. of this dilution followed by similar doses of the 1:1,000,000 dilution. This should be followed by similar doses of the 1:100,000, then 1:10,000, then 1:1,000 extracts. When the 1:100-dilution is reached, begin with 0.15 cc. followed by increases of 0.05 cc. each time. These injections should be given twice a week with the following precautions:

The amount should not be increased if the patient has much local reaction; after this type of reaction the dosage should either be repeated or reduced. Epinephrine 1:1,000 should be on hand in case a general reaction occurs; 0.50 cc. to 1 cc. may be given if necessary. The patient should remain in the doctor's office from fifteen to twenty minutes after the injection has been given.

The results of treatment with horse dander extract have, on the whole, been excellent. Patients should at the same time avoid horses and materials which contain horsehair, such as certain mattresses.

The patient, if not already immunized against diphtheria and tetanus, should be given toxoid either singly or combined so that he will be under no danger of a reaction from horse serum (antitoxin), to which he might react violently.

TOXICITY OF DICHLOROBENZENE

To the Editor:—Can you tell me whether there is danger in the use of dichlorobenzene as a moth exterminant in closets which are frequently opened? Can it be considered one of the benzene carcinogenic chronic irritants?

Jennette Evans, M.D., Ithaca, N. Y.

ANSWER.—Dichlorobenzene exists in the ortho, meta and para forms. Paradichlorobenzene is used fairly extensively in veterinary therapeutics, in agriculture and for the preservation of furs and clothing. There are few references in scientific literature to paradichlorobenzene, and it is only recently that its toxic possibilities have become of interest. A recent paper by Berliner reports the finding of cataracts following the inhalation of paradichlorobenzene vapor, and experimental investigations have led him to conclude that, when inhaled in sufficient quantities, paradichlorobenzene may produce serious toxic effects in human beings and in animals. He warns that the public, medical profession and health authorities should be made cognizant of the potential dangers. Confinement in a closed space with a high

concentration of this moth repellent may cause deleterious effects, but there is no evidence that occasional short exposures may cause untoward reactions. If a closet or room is not air tight there may be sufficient leakage to endanger nearby inhabitants: Berliner mentions a report describing the severe poisoning of a person who lived above a fur cleaning establishment. Another source of potential danger lies in the solvent sometimes used to dissolve dichlorobenzene for use as a spray. These solvents include such toxic agents as carbon tetrachloride, benzene, chloroform and carbon disulfide. The toxicology of carbon tetrachloride, benzene and carbon disulfide are discussed in a number of pharmacology books and in a textbook by Brown- ing. Present knowledge does not indicate dichlorobenzene as being a carcinogenic agent. A case of dermatitis from ortho- dichlorobenzene was reported in THE JOURNAL in 1939, and by cutaneous skin tests the patient was subsequently shown to be very sensitive to this form of dichlorobenzene. On the basis of what we now know, it is fair to say in summary that inter- mittent exposures to the fumes of paradichlorobenzene, as ordi- narily used as a moth repellent, is probably not deleterious, but there is reason to fear that prolonged exposure to this group of compounds or exposure to high concentrations may lead to injury. Clinical reports on the dichlorobenzenes are few in number, and in view of their chemical constitution and wide- spread use under varying conditions they might well be watched carefully.

NEURITIS OF TROCHLEAR NERVE AFTER INFLUENZA

To the Editor:—Following an attack of influenza a man aged 56 had a paralysis of the trochlear or fourth nerve of the eye. The only symptom is double vision when looking downward. There is a high esophoria in the lower quadrant of about 16 diopters, 8 diopters in the midline and 6 when looking upward. There is normal vision in both eyes for both near and far. The fundus is normal. The Wassermann reaction has been taken and is negative. There is a history of chronic sinusitis with allergy, seasonal hay fever. The antrum on the affected side was washed and considered negative. A roentgenogram shows more involve- ment of the left ethmoids than on the opposite side. These pictures were taken during the hay fever season. The diagnosis made was paralysis of the left fourth nerve due to ethmoiditis. Multiple sclerosis was con- sidered, but, since there was no symptom with the exception of the paralysis, all other diagnoses were eliminated. The patient can play golf and is not troubled with diplopia at any other time. As stated, the diplopia is present only when the patient is looking extremely down- ward.

M.D., Oregon.

ANSWER.—If there are no other signs or objective evidences of organic disease of the central nervous system, the patient probably has a neuritis of the left trochlear nerve. This, no doubt, followed the attack of influenza. To have this nerve involved alone is rare. Usually the ciliary muscle, the sphincter pupillae and the external ocular muscles are also involved. The paralysis may be obstinate in recovering. Thiamine hydro- chloride may be given hypodermically in doses of 100 mg. daily for at least three weeks. Large amounts of liver should be eaten. Jello at least once daily should be consumed for its aminoacetic acid content. Ephedrine sulfate, $\frac{3}{8}$ grain (0.024 Gm.) twice daily by mouth, should be tried for at least two weeks. The patient should be observed and reexamined at least once a month to determine the presence of other objective evi- dence of organic disease of the central nervous system.

DETERMINATION OF SPECIFIC GRAVITY OF BLOOD

To the Editor:—I have been asked for a simple method for determining the specific gravity of blood. This is to be used as an indicator of internal hemorrhage. I know of no accurate method for specific gravity of blood, which could be carried out in a small laboratory, which would be sufficiently sensitive to be of value. Can you tell me of such a method or where I might find it?

M.D., Oklahoma.

ANSWER.—The specific gravity of whole blood plasma and other body fluids is easily and accurately done by the falling drop method of Barbour and Hamilton. In this procedure the time required for a test fluid to fall a fixed distance in a mixture of a certain specific gravity is determined. The method is thoroughly described in numerous articles (Bellis, C. J.: A Rapid Method of Specific Gravity of Body Fluids by the Falling Drop Method, *J. Lab. & Clin. Med.* 26:564 [Dec.] 1940).

The measurement of the specific gravity of whole blood has been used to determine internal hemorrhage. The method may

reveal relatively small changes in blood volume (Foote, M. N., and Gerst, G. R.: Practical Application of the Falling Drop Method for Determining Surgical Prognosis, *Am. J. Surg.* 50:316 [Nov.] 1940).

The apparatus for determining the specific gravity of the fall- ing drop method can be obtained from laboratory supply houses.

CONGENITAL MALFORMATION OF OUTER EAR

To the Editor:—A child 2 days old has a unilateral congenital defect of the ear with absence of the external auditory meatus. The covering of this opening is like the skin elsewhere in the auricle. The entire auricle is present, somewhat smaller and a little more "crumpled" than the right ear, which is entirely normal in all respects. Whether there is a canal behind this closure, I do not know. Should one puncture this membrane with a small caliber needle to determine the presence of an external auditory canal? If so, at what age? Should suspicions of a canal arise, when (age period) and how should this be incised (type of operation)? How frequently is this abnormality encountered? How frequently is a canal found in this condition? Does one find intact hearing apparatus behind such a membrane?

Eugene Bernstein, M.D., New York.

ANSWER.—Congenital malformations of the outer ear with absence of the external auditory meatus are usually associated with absence of the drum membrane, although in rare instances the inner end of the ear canal may be developed with a drum membrane while the outer end is covered over with skin. A properly taken roentgenogram should help to indicate whether or not there is a normally developed osseous canal. Careful hearing tests with masking will reveal the condition of the hearing and will indicate whether or not the perceptive mechanism is properly developed and will give some indication of the presence or absence of a normal conducting mechanism.

Plastic reconstruction of the external auditory canal rarely results in improvement in hearing, since the drum membrane is usually not developed. Such an operation may be desirable for cosmetic reasons, especially in a boy, but it is best delayed until the age of 10 or later, when the normal development of the osseous external auditory canal is completed, and at this age accurate hearing tests can be secured.

EFFECTS OF SYNTHETIC RESINS

To the Editor:—A patient works with Plaskon molding compound, which is made by an Ohio company. This is apparently a formaldehyde for- mula of a plastic. He complains of a dry cough. Can you advise me or refer me to work on the effects of plastics on workers?

C. Spencer Bond, M.D., Rochelle, Ill.

ANSWER.—Plaskon is a synthetic resin of the urea-formalde- hyde type. In its manipulation, and particularly in hot opera- tions, gaseous formaldehyde may be evolved. Toxicity chiefly centers about this gas, although nongaseous constituents or derivatives may act as irritants or sensitizers. Dermatitis is the best known of injurious actions, although cases are infre- quent compared to some other plastic resins. Bronchitis and other forms of respiratory tract inflammation have occurred in hot molding work. Formaldehyde is the probable cause. Respiratory action, chemistry and cutaneous injuries respectively are described in the following publications:

TRAUMA AND DIABETES

To the Editor:—An infant aged 13½ months contracted diabetes mellitus. I should like to know whether a blow she received on the head six months ago could contribute to the development of the disease. A week before she became ill I gave her the first dose of whooping cough vaccine. A few days later she appeared to have a slight pharyngitis, and this became progressively worse. I put her on sulfanilamide, and the following day I discovered that she had much sugar in the urine.

Thomas Dechair, M.D., Westmoreland, Kan.

ANSWER.—A blow on the head may cause glycosuria but, fortunately, does not cause diabetes mellitus. This can be stated definitely for other reasons than the well known absence of diabetes following head injuries in war, athletics, automobile accidents and the many accidents of childhood. To cause dia- betes, at least nine tenths of the pancreas must be destroyed.

Joslin, Root, White and Marble (*The Treatment of Diabetes Mellitus*, ed. 7, Philadelphia, Lea & Febiger, 1940) give a detailed review of trauma and diabetes. The most recent dis- cussion may be found in the second edition of *Trauma and Disease* (Philadelphia, Lea & Febiger), now in press, by Braddy and Kahn, in which the chapter on trauma and diabetes was prepared by Joslin and his associates.

Vaccines and the new chemotherapeutic agencies have not been shown to lead to diabetes.

THE SUDDEN DEATH OF PATIENTS WITH FEW SYMPTOMS OF HEART DISEASE

GEORGE V. LEROY, M.D.

AND

S. SINCLAIR SNIDER, M.D.

CHICAGO

The sudden death of a patient with disease of the coronary arteries is rarely instantaneous in the sense that the person appears perfectly well one minute and is dead the next. It is instantaneous in the sense that a person with few or many symptoms suddenly ceases to live. The absence of a gradual decline in strength that might indicate a fatal outcome contributes to the unexpectedness of this type of death. In the first few hours or days after the appearance of symptoms that should suggest interference with the coronary blood supply, myocardial insufficiency is seldom severe enough to cause fatal congestive failure, and warning of impending difficulty that is obvious to the casual observer is often lacking. The type of patient we wish to discuss belongs in a strictly limited group: He does not have the dramatically severe syndrome of excruciating thoracic and brachial pain with shock and collapse. Nor does he necessarily show soon after the infarction striking evidence of congestive failure, such as pulmonary edema, orthopnea or failure of the right ventricle. The 10 whose histories we present were selected from a large number of patients observed during the past year by one of us (Dr. Snider) in the course of his routine work as coroner's physician in Cook County. These patients all died suddenly, many in the course of their ordinary activities, unattended by a physician and in circumstances that brought the death to the attention of the coroner. Such clinical information as was available, with the observations at necropsy, is presented briefly in the case histories. The pertinent data are summarized in table 1.

Symptoms which reasonably could be attributed to myocardial infarction were present in all the patients. The duration of symptoms before sudden death varied from three hours to ten days. Six patients had each consulted a physician who had interpreted the symptoms incorrectly and was genuinely astonished when the patient died suddenly. In 3 cases the patient died when a large infarct of the left ventricle ruptured. One patient was straining on a bed pan, 1 was sitting quietly

in a chair and 1 was driving his automobile. Their premonitory symptoms were no more striking than the ones experienced by patients in whom the infarct was smaller. It is outside the scope of this report to discuss the phenomenon of the development of huge infarcts with few symptoms, but it is pertinent to bear in mind that extensive myocardial destruction may occur with little obvious evidence of congestive failure. The important issue raised by contemplation of the remaining 7 patients is an adequate explanation of the mechanism of death. Three (patients 8, 9 and 10) had no readily discernible infarction of the myocardium. In them a portion of the muscle was softer than the rest and slightly discolored but no frankly necrotic changes were visible. Invariably one finds more or less recent changes in the coronary vessels that supply the softened area. It is important to emphasize here that the mode of death is no different from that which occurs with the classic syndrome of coronary occlusion during the first few days. In the remaining 4 patients (patients 4, 5, 6 and 7) the infarct discovered at autopsy was small, often no larger than the healed fibrous areas so frequently seen in the myocardium. All 7 patients in whom the ventricle was not ruptured were chosen because the infarct was either small or recent. This was done to emphasize the fact that the death of such patients can scarcely be explained as the result of loss of an important portion of the cardiac musculature.

It must be pointed out that complete obliteration of the artery supplying the infarcted region is not at all necessary. In the patients in whom the ventricle was ruptured, occlusion of a coronary artery by thrombosis was complete. In 4 of the 7 others (patients 5, 6, 9 and 10) occlusion was complete, but in 3 (patients 4, 7 and 8) there was only partial restriction of the vascular channels. Of a recently reported large series of necropsy studies¹ of hearts with myocardial infarction, only 60 per cent showed complete thrombosis of a coronary artery. The rest of the hearts had acquired the infarction as a result of changes in the vicinity of an atherosclerotic plaque or around the coronary ostia which seriously embarrassed without actually shutting off the coronary blood flow. The changes around the ostia were usually syphilitic, and those around the plaque were subintimal hemorrhages, ruptures of the plaque or hemorrhages into the area of atheroma.²

One may summarize the observations presented and the general attitude of clinicians on sudden death from cardiac disease as follows:

1. Examination of the heart of a victim of sudden death rarely fails to disclose lesions in one or more of

the coronary arteries which impede or obstruct the blood flow. In location and extent these lesions often cannot be distinguished from similar ones in patients dead from other causes.

2. The myocardium of a victim of sudden cardiac death nearly always contains an infarct. In the relatively few instances in which there are no symptoms antecedent to death, neither a softening nor a clearly demarcated infarct may be found in association with the vascular lesion. In all patients who have had symptoms—however mild—for a few hours or more before death, the myocardium is damaged. The infarct if early is simply a softened darker red area with some dilatation of the arterioles in the overlying epicardial fat; or there may be a discrete region of muscular necrosis with hemorrhagic discoloration and fatty changes. The infarct may be of any size and in any position; in this respect it differs in no way from the fibrous scar of a healed infarct that is seen so frequently.

In an effort to explain the paradox that presumably identical cardiac vascular and muscular lesions may or may not cause sudden death, most writers have assumed

The effect of the ligation of a coronary artery of dog has been studied by many workers. The number of animals that survived after ligation of the circumflex branch of the left coronary artery varied considerably. In table 2 are collected some of the earlier data. In 1939 Hall and his colleagues⁴ reported the first of great many experiments in which ligation was performed on conscious animals through the tightening of a previously applied loose ligature. In general the workers were studying alterations in mortality that followed various disturbances of the innervation of the heart. When one of us (Dr. LeRoy) in 1940 commenced a study of this problem, an attempt was made to prepare anesthetized animals which would have the same mortality as conscious ones. The considerations behind this step were not entirely humanitarian. It was thought, however, that the subjective sensation of pain evidenced by the conscious dog might reinforce an existing reflex or even initiate one. The fact that use of anesthesia with morphine and pentobarbital sodium resulted in the same mortality as that for conscious dogs seems to indicate that the sensation of pain

TABLE 1.—Summary of Case Histories

Patient	Age	Sex	Symptoms		Autopsy		Medical Case
			Duration	Type	Myocardium	Arteries *

the intervention of some sort of a reflex disturbance of cardiac function severe and sudden enough to prove fatal. Ventricular asystole and ventricular fibrillation³ have been demonstrated as the terminal mechanism in the few instances in which electrocardiograms were being made when death occurred. The majority of patients died with ventricular fibrillation, but the mode of its development has not been clearly understood. It is obvious that insight into the causation of this fatal arrhythmia should provide clues to aid one in combating its onset. The greatest difficulty in reconstructing the series of events responsible for a sudden death is that this must be done in retrospect, with only dead tissues as building materials. Other difficulties are the variability of the vascular and muscular lesions and—as we have indicated—the fact that similar lesions may not cause death. Finally, it is apparent that age, physiologic condition and inherent biologic differences must be important determining factors. Animal experimentation eliminates fairly well most of the confusing factors except the inherent ones. We think these are the most important.

a by-product rather than an essential feature of the mechanism of sudden death. This phase of our work was prompted by study of patients of the type referred to earlier, in whom pain was a minor element in the series of events that followed occlusion of a coronary artery.

In our laboratory a strictly standardized procedure is followed for the production of acute coronary occlusion. After the induction of morphine and pentobarbital sodium anesthesia (aseptic precautions being observed) in a dog a ligature is placed on the circumflex branch of the left coronary artery. Subsequently the heart may be left exposed for direct observation and color photography.⁵ In other dogs the thorax was closed, and the effect of certain drugs on survival was studied. With a large number of such preparations the mortality after coronary occlusion was 75 per cent. The value is the same as that found by Hall and by us for conscious animals. In the discussion of our results, and

in our comments on Hall's work, the phrase sudden death will be applied to animals which died within twenty-four hours after ligation of the circumflex branch. All mortality referred to concerns only cases of sudden death.

The sequence of events after the occlusion of the circumflex branch of the left coronary artery is as follows:

1. At the instant of occlusion the blood pressure falls suddenly, and a shower of extrasystoles or well defined bradycardia appears during an interval of about fifteen seconds. The electrocardiogram is usually unchanged for at least thirty seconds. The conscious dog may or may not experience pain.
2. One minute after occlusion the blood pressure may be lower or normal. A well demarcated zone of ischemia is present in the part of the heart deprived of its blood supply. Typical electrocardiographic changes are occurring: elevation of the RS-T segment in all leads, with exceptionally high elevation in leads 2 and 3. The pulse is generally more rapid, and a variable number of extrasystoles occur.
3. Five minutes after occlusion the blood pressure is usually falling; the pulse is more rapid, and showers of extrasystoles and short runs of ventricular tachycardia are seen in most dogs. The myocardial infarct is deeper in color, and the ischemic myocardium bulges outward during systole. The electrocardiographic changes are more prominent. In the conscious dog there is usually evidence of more or less pain, altered respirations and struggling.
4. At any time after five minutes one can see little further alteration in the situation. The infarct may become somewhat darker, and the arrhythmias are more frequent and more prolonged. In the animal destined to die suddenly the only difference one can see is a greater amount and variety of arrhythmias.
5. Suddenly the entire uninfarcted part of the myocardium is seen to swell; dilation of the heart is occurring. The uninvolved part of the myocardium at the same time becomes darker until the margin of the infarct disappears. The contractions of the ventricle become feeble, rapid and irregular, and paroxysmal ventricular tachycardia is recorded electrocardiographically. Suddenly a portion of the uninfarcted area of the myocardium begins to fibrillate, and in a few seconds the process spreads until generalized ventricular fibrillation is established. The blood pressure has then fallen to zero, and the dog, after giving a convulsive gasp, is dead.

This description is a synthesis of about fifty observations made on conscious animals and on suitably anesthetized ones with the heart exposed. Colored motion pictures of many preparations were taken and studied

vasoconstriction subsequent to the myocardial infarction. This is clearly seen in the animal (and is shown in the colored pictures) when the uninfarcted part of the myocardium gradually becomes as dark as the infarct just before ventricular fibrillation commences. The existence of such a coronary vasoconstriction has been demonstrated by us in other experiments, in which the

blood flow in one coronary artery was measured with a thermostromuhr while another artery was ligated. It seems apparent to us that the ischemia of the myocardium is provoked by a reflex coronary vasoconstriction and that it is the factor that causes ventricular fibrillation in the animal whose myocardium is susceptible to the development of this arrhythmia. The main pathways of the reflex arc may be inferred from existing data. Many workers have shown that painful afferent impulses from a myocardial infarct travel centrally through the cardiosensory nerves, the stellate ganglions and the upper five or six thoracic sympathetic ganglions. These workers have shown also that cardiosensory denervation prior to infarction reduces the mortality strikingly. The efferent impulses provoking vasoconstriction must travel from the brain to the coronary arteries in the vagus nerves, since they are the only generally accepted conductors of such activity.

Many experiments were performed in Hall's laboratory and in ours in an attempt to modify the incidence of sudden death after experimental coronary artery occlusion. In table 3 are collected the data. The greatest reduction in mortality occurs when the afferent portion of the lethal reflex arc is interrupted surgically: Bilateral removal of the stellate ganglions and the upper five thoracic sympathetic ganglions reduced the mortality in conscious dogs from a control value of 75 per cent to only 10 per cent. Unilateral sympathectomy reduced the mortality to only 33 per cent. Surgical ether anesthesia sufficiently depresses all reflex activity, so that ligations in which it was used resulted in a mortality of only 25 per cent. On the other hand, light anesthesia with morphine and pentobarbital sodium had so little influence on the reflex in question that the mortality was the same as for conscious dogs, 75 per cent. Administration of atropine sulfate in appropriate

carefully. In every respect our description of the sudden death of a dog with experimental coronary occlusion agrees with that published by the Toronto workers. One feature that we have seen is that when death occurs rapidly—that is in less than thirty minutes—no infarct is visible afterward, whereas if the dog survives longer a distinctly darker infarct is found.

The main feature of the experiments is the clear demonstration that there is a generalized coronary

doses reduced the mortality to about 35 per cent. A death rate of 25 per cent was observed after the administration of active coronary vasodilating drugs, the xanthine derivatives theobromine and theophylline. When atropine sulfate and theophylline with ethylenediamine were used, the death rate, in conscious dogs, was 30 per cent. Use of quinidine sulfate, which has no action on either the coronary vessels or the reflex arc, reduced the mortality to only 55 per cent.

From the experiments described one can safely conclude that sudden death after ligation of a coronary artery is due to ventricular fibrillation.⁶ This arrhythmia is caused by generalized myocardial ischemia, which is accomplished by active vagal coronary vasoconstriction. This unfortunate stimulation of the vagus is produced reflexly by afferent impulses arising in the myocardial infarct and transmitted centrally through the sympathetic nerves. Amelioration of the vagal vasoconstriction, whether by cardiosensory denervation, by the use of atropine, by deep surgical anesthesia or by active coronary vasodilatation secured with the xanthine drugs, reduces the incidence of sudden death appreciably. The extent to which the reflex operates in the absence of efforts to interfere with it depends on certain inherent biologic phenomena: the stimulation threshold of the cardiosensory sympathetic nerves, the tone of the vagus and the susceptibility of the uninfarcted part of the myocardium to the influence of ischemia. Certainly these factors are difficult if not impossible to evaluate.

We think it is perfectly reasonable to apply to human beings the information derived from our studies on dogs. In each one observes the same unpredictable outcome from apparently similar lesions. In each sudden death is obviously not due to simple failure of the contractile power of the myocardium in the infarct alone. In most cases in which sudden death of a patient with recent coronary occlusion has been studied electrocardiographically, the same mechanism—ventricular fibrillation—has occurred that we have seen in the dog. Therefore it is reasonable to employ the means discovered by experimentation on the dog in an attempt to reduce the mortality among patients.

We think the data we have presented are important for two reasons. First, the realization that reflex phenomena are responsible for the sudden death of a patient with myocardial infarction is valuable. Appreciating this, one should be less prone to pass over lightly mild symptoms or mild physical signs that suggest coronary artery disease. Bearing in mind that these mild symptoms may be the sole evidence of an infarct that can at any moment initiate fatal ventricular fibrillation, one will be less likely to ignore them. The sudden onset in a previously healthy person of substernal oppression, mild pain, symptoms of indigestion or brachial pain or discomfort unrelated to injury should arouse suspicion. Suspicion should be doubled if the symptoms are aggravated by exertion, especially if they are associated with dyspnea. Dyspnea and fatigue occurring suddenly and experienced under conditions under which it is not usually felt should always excite suspicion. With suspicion aroused, the patient should be examined with great care. We have little doubt that most patients with mild symptoms of myocardial infarction have some discoverable cardiac abnormality, such as showers of extrasystoles, pulsus alternans, perhaps a friction rub

and a blood pressure lower than the usual reading. If facilities are available an electrocardiogram should be made, and small deviations from normal—particularly in the RS-T segment—should be given serious consideration. The most important point clinically is that suspicion rather than certainty should govern one's conduct.

The second reason why we attach significance to the facts presented is that an answer is supplied to the question of the physician who says "All right, this patient may have a myocardial infarct; but what can be done about it while the symptoms and signs are so indefinite except to wait and see and to meet whatever situations arise?" The fault in this attitude, of course, is that the first serious change in the patient's status may be the onset of fatal ventricular fibrillation! The animal studies offer some indications of useful, reasonable therapeutic measures, and from them we have learned that certain agents are available which will minimize or counteract the lethal reflex. Rest alone for the patient suspected of having a myocardial infarct is undoubtedly valuable, because it decreases the demand of the myocardium for blood and thus lessens the effect of any coronary vasoconstriction that might occur; but rest is not enough. Atropine and the coronary vasodilator drugs, such as the salts of theobromine and theophylline, can be given in large amounts by several routes and with no risk. The doses of these drugs that we have used for dogs are approximately equivalent to the doses for human beings. Of atropine sulfate we give dogs about one half the atropinizing dose, or 0.1 mg. per kilogram of body weight. As to patients, one-half the atropinizing dose is about 0.8 mg. ($\frac{1}{15}$ grain), given intravenously, for the usual adult. Of aminophylline (theophylline with ethylenediamine), for example, we give patients and dogs an initial dose of 5 to 10 mg. per kilogram of body weight intravenously. The usual amount for an adult is 0.48 Gm. in 20 cc. of solution, given intravenously and slowly. The injection may be repeated every four or six hours as the situation suggests. Surely in case of doubt one can do no harm by giving such amounts of atropine and a xanthine derivative while one waits to see what will happen or while one waits for an electrocardiogram to be made. Naturally not all patients who are so treated will survive; but if the same ratio observed in dogs should hold for human beings 1 of 3 will die, instead of 3 of 4. The reduction in mortality is certainly a worth while advantage. It is hard indeed for us to escape the conclusion that many victims of heart attacks whom the coroner's physician sees would not have died had atropine and one of the xanthine derivatives been given and complete bed rest insisted on soon after the onset of the symptoms.

CONCLUSIONS

1. The myocardial infarct responsible for sudden death need not be so large that muscular failure alone is responsible.
2. Myocardial infarction may occur without complete closure of a coronary artery and without the classic syndrome of pain, shock and collapse.
3. A myocardial infarct usually causes some symptoms, even though they may be mild.
4. The sudden death of a patient with infarction of the myocardium is due to a reflex coronary vasoconstriction whose stimulus is the infarct, whose afferent pathway is the cardiosensory innervation and whose efferent pathway is the vagus. The result of this reflex vasoconstriction in a susceptible person is fatal ventricular fibrillation.

6. In our experiments a few instances of partial auricular-ventricular block were seen, but in no case in which death was observed was this the terminal mechanism. The experience of Hall and his associates⁴ was similar.

5. The probability of the establishment of this lethal reflex may be decreased by use of certain drugs (atropine and the xanthine derivatives), by cardio-sensory denervation and reasonably but to a lesser extent by simple rest in bed.

REPORT OF CASES

CASE 1.—A man aged 50 had complained for about one week of slight but increasing substernal pain. Three days before death increasing dyspnea, orthopnea and more severe pain occurred. He was up and around during the entire time but had received no medical care.

Necropsy disclosed moderate hemopericardium, the origin of which was a small perforation of an aneurysmal dilatation of an infarct of the lateral wall of the left ventricle. Complete occlusion by a thrombus of the descending branch of the left coronary artery was found.

CASE 2.—A man aged 56 ran into a tree while driving home from work. He was dead when passersby reached the wreck. Three days previously he had consulted a physician because of a "cold in the chest" and had received some sort of medication.

Necropsy disclosed moderate hemopericardium, the origin of which was a large rupture of an infarct of the posterior surface of the left ventricle. A complete occlusion of the more distal portion of the circumflex branch of the left coronary artery by a thrombus was observed.

CASE 3.—A woman aged 60 was bedridden, convalescing from a seven week old fracture of the femur. Ten days before death she complained of substernal tightness to her physician, who visited her regularly. This was diagnosed and treated as a "flu-like cold in the chest." Three days before death she had increasingly severe substernal pain, coughing and dyspnea. She died suddenly while getting off a bedpan.

Necropsy disclosed moderate hemopericardium, the origin of which was a large rupture of an infarct at the apex of the left ventricle. A complete occlusion by thrombosis of the anterior descending branch of the left coronary artery was observed. This had formed on a calcified atherosclerotic plaque 1 cm. below the origin of the vessel.

CASE 4.—A man aged 45, a pharmacist, had had a headache all day and had felt tired. About an hour before death he experienced a constant tightness in his chest. He fell over suddenly behind a counter, dead.

Necropsy disclosed a 2 by 3 cm. infarct at the apex of the left ventricle. The anterior descending branch of the left coronary artery was incompletely occluded by an atheromatous plaque, elevated by a fresh subintimal hemorrhage. The left coronary artery was small in caliber, less than one-half the usual size. The posterior wall of the left ventricle was supplied almost entirely by a large branch of the right coronary artery.

CASE 5.—A man aged 41, a linesman, died suddenly at work on a pole. His widow stated that for the preceding four days he had complained of breathlessness and of "neuralgia" in his left arm, aggravated by exertion. He had seen a physician on the morning of the day of his death and had received some pills.

Necropsy disclosed a small infarct, about 2 by 3 cm. in size, with beginning fatty necrotic changes at the apex of the heart involving the septum. A small thrombus attached to an ulcerated atherosclerotic plaque partly occluded a posterior descending branch of the right coronary artery.

CASE 6.—A man aged 39, a milkman, experienced moderately severe pain across the chest and in both arms the day before he died. Despite this pain he was able to finish his deliveries. On his way home he saw a physician, who gave him some pills. He slept poorly but went to work the next day. He was found dead on a prairie a short distance from the start of his milk route.

Necropsy disclosed a 3 by 4 cm. infarct on the lateral wall of the left ventricle. The circumflex branch of the left coronary artery was completely occluded by a thrombus fixed to an ulcerated atheroma.

CASE 7.—A woman aged 32 became nauseated while sitting quietly at home. With the gastrointestinal disturbance there was some substernal tightness and a sensation of fear. A physician was called who diagnosed "intestinal flu" and prescribed some medicine. She lay down to rest and was found dead four hours after the onset of symptoms.

Necropsy disclosed a large infarct of the posterior, apical and septal regions of the left ventricle. The ostium of the left coronary artery was reduced to a diameter of 1.5 mm. by an encircling gumma. The ostium of the right coronary artery was completely obliterated by a recent subintimal hemorrhage in the syphilitic infiltration of this region. Large gummatous pads, some with recent subintimal hemorrhages, encircled the root of the aorta and separated the attachments of the valves.

CASE 8.—A man aged 49, a bricklayer, died suddenly at work. During the preceding week or ten days he had complained of moderate precordial pain on effort. About a year earlier he had suffered from what was diagnosed as coronary occlusion, but the electrocardiogram was asserted to have been "negative."

Necropsy disclosed a slight softening of the apical region, with no distinct infarction. The small blood vessels in the epicardial fat of this region were widely dilated. The anterior descending and the circumflex branches of the left coronary artery were completely occluded by old calcific lesions. There was a diffuse fibrous scar in the posterior wall of the left ventricle. The right coronary artery was smaller than usual, and anomalies of both arteries were seen.

CASE 9.—A man aged 41, a salesman, became sick at work, with gastrointestinal disturbances, substernal pain and little or no evidence of shock. He was taken to a hospital, where his symptoms decreased after morphine was given. He suddenly collapsed and despite efforts at resuscitation died suddenly three hours after the onset of symptoms.

Necropsy disclosed a recent barely discernible infarct of the posterior wall of the left ventricle and of the septum. This was apparently due to occlusion by fresh thrombi attached to atherosclerotic plaques in the circumflex branches of both coronary arteries. There was an old fibrous scar, 3 by 4 cm. in size, in the anterolateral wall of the left ventricle. This was in relation to an old, fibrous, complete occlusion of the anterior descending artery.

CASE 10.—A man aged 43 died suddenly while changing his clothes before starting to work in a factory. He had complained that discomfort in the upper part of the abdomen had awakened him, and he had eaten no breakfast. He had a flannel binder pinned about his abdomen.

Necropsy disclosed a faintly defined infarct around the base of both ventricles and in the region of the septum adjacent. The discoloration extended into the interauricular and the inter-ventricular septums. No septal branch of the left coronary artery could be found. There were two tiny aberrant ostiums in the anterior sinus of Valsalva in addition to the ostium of the right coronary artery. Vessels from the two small ostiums, almost completely occluded by fresh subintimal hemorrhages, were traced to the infarct.

1713 West Ninety-Fifth Street.

ABSTRACT OF DISCUSSION

DR. G. K. FENN, Chicago: The paper of Drs. LeRoy and Snider has attracted my attention for two reasons. First, I have been greatly interested in reflex effects on the coronary circulation. I suspect that such effects may be initiated in many places, both in the heart and from extracardiac sources. Two years ago, before this section and on the same program with Dr. Hall, Dr. de Takats and I submitted evidence which led us to believe that reflex coronary constriction accompanied pulmonary embolism. Last year Drs. Gilbert, LeRoy and I tried to convince this section that we had demonstrated the occurrence of such reflexes arising in the gastrointestinal tract. Now, Drs. LeRoy and Snider have built up a rather clearcut case to show that patients die following unsuspected interference with the coronary circulation and that many of these deaths are not due to the infarct per se or to congestive heart failure. They have integrated these occurrences into experimental work

which seems to indicate quite clearly that many of these deaths are due to reflex coronary constriction with its attendant phenomena, notably ventricular fibrillation. I do not see how we may disregard any longer the importance of these reflex effects. I am interested secondly because of the altered therapeutic approach to the problem that has grown out of all this work. Not long ago morphine was the only drug that received much attention in the treatment of acute coronary occlusion. Now morphine does not overcome the reflex constriction. Indeed, it has been accused of accentuating such effects. Certainly morphine did nothing toward saving the life of the experimental animals. It seems clear therefore that, when morphine must be used, and it frequently must be or is used, something should be added to offset its vagal action. Dr. LeRoy has pointed out the advantages derived from atropine and drugs of the xanthine group. Incidentally, it is surprising how much less morphine is necessary in the management of acute coronary occlusion when the reflex is overcome by the use of atropine and theophylline plus the inhalation of oxygen. I do not believe that the importance of these reflex effects is sufficiently appreciated by the medical profession in general. No harm can come from the application of these remedies to patients for whom the diagnosis is uncertain. The great harm arises in not considering the possibility of an interference with the coronary flow.

DR. HAROLD E. B. PARDEE, New York: There are two parts to this paper, both of importance. The first part calls our attention to the frequency of sudden death of patients who have had only minor symptoms referable to the heart. The preliminary symptoms are due to coronary insufficiency, and we must learn to recognize such symptoms as possibly due to serious coronary occlusion. In these patients we must particularly look for three important diagnostic features: arrhythmia, fall of blood pressure and electrocardiographic changes. Pulsus alternans and pericardial friction are also of importance but are unfortunately rare. We should make a special effort to obtain the electrocardiogram in these cases because the record will often give an indication of myocardial abnormality in cases that are otherwise negative. It is important to emphasize in this connection that, when the limb leads are normal, if we take two precordial leads, one from the parasternal position and one just beyond the apex, we shall obtain positive findings in 12 or 13 per cent of additional cases. The second part of the paper, on the experimental work, confirms the importance of a reflex mechanism in producing the sudden death which occurs not only among patients who have had only slight symptoms due to coronary insufficiency but also among those who have had cardiac infarction with severe symptoms. Certain therapeutic recommendations are based on this experimental work. It is most important to give an adequate dose of atropine in these cases. The initial dose should be at least $\frac{1}{15}$ grain (1 mg.) or, better, $\frac{1}{50}$ grain (1.3 mg.) and the effect may be continued by $\frac{1}{100}$ grain (0.4 mg.) every four or six hours. An adequate dose of the xanthines is also important. We should give from 5 to $7\frac{1}{2}$ grains (0.3 to 0.5 Gm.) by mouth or the same dose intravenously, provided it is given slowly. Doses of this size are necessary to produce the definite therapeutic effects that are needed in such cases. I feel that the correlation of clinical observation and experimental work in this paper is an ideal of what medical research should be and that the therapeutic conclusions Dr. LeRoy has drawn from this work deserve strong consideration.

DR. GEORGE V. LEROY, Chicago: I was pleased that Dr. Fenn brought up the question of the role of morphine, because it is a complicated problem that we have not completely worked through, using the technic we have described here. It should be observed, though, that to get the same mortality in dogs anesthetized with pentobarbital sodium as occurred in conscious dogs it was necessary to add a definite amount of morphine. If the dogs received pentobarbital sodium alone the mortality was between 30 and 40 per cent, about half way between that of dogs under surgical ether and conscious dogs. Morphine definitely made the dogs more liable to die and was used deliberately in preparing these animals. The other thing that I think bears repeated emphasis is the fact that myocardial failure, as seen by the classic signs of edema, cyanosis and dyspnea, is a

rather minor feature during the first few days in the majority of patients with myocardial infarctions, especially the patients we talked about with small infarcts. Certainly, in the autopsies of these patients, pulmonary edema and hepatic congestion were the exception rather than the rule. I was pleased to have Dr. Pardee recommend the larger doses of drugs. It is our custom clinically, in the use of atropine to give an additional dose of from $\frac{1}{50}$ to $\frac{1}{45}$ grain intravenously. The patient is then maintained in atropinization by $\frac{1}{100}$ to $\frac{1}{50}$ grain at appropriate intervals. The doses of the xanthines in our practice are about $7\frac{1}{2}$ grains every four to six hours in recent occlusions, which parallels very closely milligrams on a kilogram basis, the amounts we used to achieve the results in the dogs.

SIMILARITIES AND DISTINCTIONS BETWEEN SHOCK AND THE EFFECTS OF HEMORRHAGE

DONALD MCGREW, M.D.

PHILADELPHIA

Clinical similarities between shock and the effects of hemorrhage are so numerous that some authorities have regarded the two as identical. It is believed by many that hemorrhage will produce the complete syndrome of shock—a belief which we formerly supported.¹ We supposed that anoxia in the tissues resulting from the effects of hemorrhage would cause endothelial permeability, hemoconcentration and other features characteristic of shock. Blalock² had reported such results, and these coincide with our belief as published; but attempts to substantiate that belief experimentally produced results which were not anticipated.

We made the simple experiment of withdrawing measured amounts of blood from the femoral veins of an unanesthetized dog (no. 338) weighing 10 Kg., allowing intervals of time for physiologic readjustment of the circulation. Erythrocyte counts and hemoglobin determinations were made (by the photoelectric method) before and at intervals during the experiment. Examinations of the blood, including one of the last sample drawn, revealed progressive dilution.

Successive repetitions of the experiment, greater care being taken to approach the death point gradually, gave similar results. Eight dogs were used in unsuccessful attempts to demonstrate a terminal hemoconcentration as a result of simple hemorrhages. The data are summarized in table 1.

It may be seen that dogs vary in their sensitivity to loss of blood. The loss necessary to cause death within twelve to sixty-seven hours ranged from 5.58 to 9.1 per cent of the body weight, but no relation is apparent between this variation and the duration of the experiments. Postmortem examinations were made immedi-

ately, and the visceral appearances in each instance were those characteristic of hemorrhage. The tissues were ischemic, pale and dry; there was no engorgement of the minute vessels, edema, effusions or petechiae. No parenchymal necroses were found by microscopic examination in any of the tissues. Data on these visceral changes were substantiated in all the subsequent experiments on hemorrhage.

In another series the dogs were anesthetized by an intravenous or an intraperitoneal injection of 0.035 Gm. of amytal per kilogram of body weight in order that a continuous record of the arterial blood pressure after hemorrhage might be made. The dogs were bled in measured amounts at intervals from the femoral artery or vein. The duration of the experiment, from the first bleeding to the death of the animal, ranged from four to thirty-one hours. In the experiments of long duration, several bleedings were done on the preceding day, with the dogs in a normal state. Anesthesia and blood pressure readings were initiated only in the last four to six hours of the experiment. The maximal period of anesthesia in the group was six and five-tenths hours. Data procured under these conditions are shown in table 2.

In all instances the viscera were pale, dry and ischemic; no edema, congestion or petechial hemorrhages were found in any tissue at necropsy. The with-

other investigators and of features developing under experimental conditions. Surprisingly few data are on record concerning physiologic disturbances associated with either shock or hemorrhage, and no detailed comparison of these has been found.

SUSCEPTIBILITY TO HEMORRHAGE

A comparison was made between the response to hemorrhage by a dog in shock with the blood pressure at the critical level and that of a dog with the blood pressure at the same level from repeated hemorrhages. A dog weighing 13.6 Kg. was anesthetized with 0.035 Gm. of amytal per kilogram of body weight, and an arterial cannula was connected to a mercuric manometer for a continuous record of the blood pressure. Muscle pulp, 4.5 Gm. per kilogram of body weight, was then introduced into the peritoneal cavity. Nine hours later, when the mean blood pressure had declined to 72 mm. of mercury, the animal died within two hours from three bleedings of 10, 15 and 10 cc. respectively at intervals of thirty minutes.

In contrast, a dog weighing 11.6 Kg. was subjected to five repeated bleedings totaling 370 cc., or 3.2 per cent of the body weight, which reduced the pressure to 70 mm. Subsequently, five withdrawals of 20 cc. each, one of 15 cc. and eight of 10 cc. each at intervals of twenty to thirty minutes caused death. In other words, this dog withstood the loss of 195 cc. of blood during five hours after the blood pressure had been reduced to a critical level by previous hemorrhages. Death occurred thirty minutes after the last withdrawal of 10 cc. Hemodilution was progressive; at no time did the erythro-

TABLE 1.—Effects of Hemorrhages in Unanesthetized Dogs

347	7.9	7.78	32.5	76

* In this and the following tables weights are shown in kilograms and the amount of blood drawn is shown as percentage of the body weight

drawal of a smaller total volume of blood produced death, and the hemodilution was much less than in unanesthetized dogs. This is exemplified in a comparison of dogs 346 and 373 (table 3).

It may be seen from the comparison that a loss of blood amounting to 9.1 per cent of the body weight caused 77 per cent hemodilution and death in thirty-one and one half hours without anesthesia, while half as great a loss of blood caused death in thirty-one hours the last six and one half of which the dog was under amytal anesthesia. The hemodilution was less than half that shown by the unanesthetized dog. The reactions of anesthetized animals were significantly different from those of unanesthetized ones. In 2 instances, after hemorrhages totaling 2.6 per cent and 2.2 per cent of the body weight respectively the blood remained at approximately the same concentration as before bleeding, and in 2 others a slight temporary rise followed by a decline in the concentration occurred.

Significant differences were noted between the behavior of dogs after hemorrhages and that of dogs in a state of shock from the absorption of tissue substance. The former were active and did not appear ill; there was no vomiting, diarrhea or evidence of urinary disturbance. Dogs in shock uncomplicated by narcosis are inactive and manifest each of the features of illness mentioned. These apparent contrasts led us to make further comparisons, both of observations recorded by

TABLE 3—Comparison of Two Dogs

346 (not given anesthetic)	10.0	9.1	31.5	77
373 (given amytal)	10.8	4.48	31.0	32

cyte count of the hemoglobin content rise above the value noted in a previous examination. The results of the experiment are shown in figures 2 and 3.

The foregoing results illustrate an observation frequently made: that a person or an animal in shock may not survive a slight loss of blood which under other conditions would not be serious, and that hemorrhage when present is a contributory factor of highest importance.

LYMPH FLOW, TISSUE FLUID AND FLUID BALANCE

Some fifty years ago Heidenhain³ observed that injections of diverse substances increased the flow of lymph. Other significant features of his report have escaped attention. He noted that the injections caused also a decline in the blood pressure and an increase in

Fig. 2.—Blood pressure during shock. The scale at the left shows arterial pressure in millimeters of mercury. Loss of blood is indicated volumetrically by the height of the shaded columns; clock time is shown at the bottom. After the pressure had declined to 72 mm. three successive bleedings totaling 35 cc. caused death.

the total solids of the blood—hemoconcentration; the period of lowest blood pressure coincided with that of the maximal flow of lymph. Among the substances which produced these results were watery extracts of normal tissues, such as muscle, liver, spleen, kidney and mucosa, and bile, peptone and other secretions.

Subsequent studies (by Starling⁴ and by Drinker and Field⁵) have shown that the increased flow of lymph, its high protein content, the decreased blood pressure and plasma volume and the hemoconcentration result from the leakage of plasma through capillary walls rendered abnormally permeable by the effects of the agents used. It has been shown that Heidenhain's "lymphagogues" and other substances which cause endothelial damage will produce the complete syndrome of shock if given in sufficient doses.

The following experiment illustrates the effect of shock on lymph flow.

A dog weighing 14 Kg. was placed under continuous ether anesthesia, the ether being administered through a tracheal tube, and the thoracic duct was cannulated. The rate of lymph flow was found to average 0.4 cc. per minute during a thirty minute period. The specific gravity of this lymph was 1.016, and it contained 420 cells per cubic millimeter. Seventy Gm. of muscle was excised from the dog's gluteal region, care being taken to avoid loss of blood by hemorrhage. The muscle was finely ground in a meat chopper, suspended in 150 cc. of physiologic solution of sodium chloride and introduced into the same dog's peritoneal cavity. During the ensuing two hours the rate of lymph flow averaged slightly more than 1 cc. per minute—an increase of 150 per cent. The specific gravity had risen to 1.018 and the cell content to 4,080 per cubic millimeter. The lymph became salmon colored, then pink, then finally bright red because of a progressive increase in the content of erythrocytes. Likewise, the coagulability of the lymph increased noticeably, so that it clotted frequently within the cannula, notwithstanding the increased rate of its flow. During four hours the hemoconcentration increased more than 20 per cent.

as was shown by determination of the hemoglobin content and by counts of red cells. Similar changes in the flow and character of the lymph resulted when the experiment was repeated.

The effect of hemorrhage in another experiment performed under comparable conditions showed a striking contrast.

A dog weighing 21.8 Kg. was similarly anesthetized, and cannulation of the thoracic duct gave an average lymph flow of 0.66 cc. per minute during one hour. During the ensuing hour the dog was bled at intervals in amounts totaling 345 cc., 1.6 per cent of the body weight, or about 22 per cent of the estimated blood volume. During the next two hours the rate of lymph flow was only 0.21 cc. per minute—a decrease of 68 per cent. The lymph became lighter in color and did not coagulate spontaneously.

This substantial reduction in the flow of lymph and change in its composition are diametrically opposite to the change which accompanies shock. These results coincide with the observation of Starling that the formation and flow of lymph are decreased after hemorrhages.

The water content of various tissues was determined by weighing accurately the fresh, finely minced substance, desiccating it completely and weighing the residue to determine the water loss. Care was exercised in taking the specimen from the same area, e. g. the muscle or bowel, in each instance. Lung was not included in this comparison because the fluid content of the lobes varies and it was found technically difficult to desiccate the entire organ.

It was found that the skeletal muscles, liver and bowel wall contained more water after shock than after death by hemorrhages. Other investigators have recorded that these tissues become dehydrated after hemorrhages. Differences in the water content of the kidneys and pancreas were insignificant. An increase in tissue fluid was emphasized by Eppinger⁶ as a regular occurrence in shock from trauma and from other causes. The fluid had a high protein content, and its chemical composition closely approximated that of plasma.

Fig. 3.—Blood pressure after hemorrhage. Three bleedings, producing 100 cc. of blood each, were done on the preceding day. After aural anesthesia had been done the withdrawal of 70 cc. of blood brought the arterial pressure to 70 mm. A further loss of 195 cc. of blood, drawn in fourteen successive bleedings, was required to cause death.

Blalock reported the production of edema by hemorrhages, but we have not found confirmation of this in the observations of others. Physiologists agree in stating that hemorrhage is followed immediately by a

transfer of fluid from the tissues to the blood. By this physiologic means for counteracting the effects of hemorrhage the lost blood volume is restored, but the water content of the tissues is reduced correspondingly. At necropsy the tissues are described regularly as ischemic and dry when uncomplicated hemorrhages have caused death.

A serious derangement of fluid balance is evidenced by the increased flow of lymph, the increase in tissue fluid, the hemoconcentration and the disturbance of absorption which accompanies shock. This derangement apparently has escaped the attention of most authors, for we have seen no discussion of it in the voluminous literature pertaining to the dynamics of shock. Several physiologic forces participate in maintaining normal relations between intravascular and extravascular fluids. But the action of these forces depends primarily and essentially on the presence of a semipermeable membrane between those fluids. Abnormal permeability of the endothelium throws out of gear the entire mechanism of fluid balance. The disturbance develops simultaneously with circulatory deficiency resulting from capillary injury, and it interrupts the process of absorption. Failure to absorb fluid from the tissues and from the gastrointestinal tract results in hemoconcentration—a characteristic sign of shock. Furthermore, the loss of fluid by vomiting, perspiration and diarrhea is not compensated readily. Fluids given intravenously leak out into the tissues, accentuating the edema without relieving the hemoconcentration.

Patients or animals affected by simple hemorrhages will absorb fluids from the tissues and from the gastrointestinal tract, thus restoring the blood volume. Suitable fluids given intravenously will be retained, because endothelial permeability has not been increased and the mechanism of fluid balance is not notably impaired.

COAGULABILITY

All the recorded observations we have found indicate that the coagulation time is appreciably lengthened during shock. This has been noted after burns, peptone poisoning, anaphylaxis and injections of histamine, as well as in the case of traumatic and experimental shock. Popielski⁷ emphasized this feature and cited an instance in which blood from an animal in shock remained unclotted for sixty-four hours. Howell⁸ commented on the low coagulability of the blood in anaphylaxis and after injections of protein cleavage products, peptone and histamine. He explained this as due to excessive mobilization of heparin from the liver. Perhaps the explanation applies also to delayed clotting in shock from other causes. We found the speed of coagulation noticeably retarded in 10 of 12 dogs tested during shock. One animal showed more rapid coagulation, and 1 showed no significant change.

After hemorrhages the formation of fibrin is accelerated and the clotting time is shortened.⁹ The acceleration is detectable within ten minutes after the hemorrhage.¹⁰ In our experiments, the blood of dogs clotted normally in eight to twelve minutes. After each successive bleeding the coagulation was more

rapid, and when the blood pressure had declined to the critical level the blood clotted completely in one to four minutes. A decided increase in the speed of coagulation occurred after hemorrhages in 9 of 10 dogs on which observations were made. In 1 dog no significant change occurred.

BLOOD CHEMISTRY

An increase in the nonprotein nitrogen content of the blood during shock was first reported by Duval and Grigaut¹¹ (1918). This was confirmed by Aub and Wu and by others. Whipple and Van Slyke¹² found that the increase consisted largely of urea, amino and peptid nitrogen. Other investigators have shown that the creatinine content is also increased. These changes occur with traumatic shock, burns, intestinal obstruction and anaphylaxis and after injections of commercial peptone and of histamine. Lurje¹³ found an increased nonprotein nitrogen content in the blood during shock after surgical operations in 8 patients. The level returned to normal when the circulatory deficiency was relieved. Whipple attributed the rapid piling up of nitrogen in the blood to a rapid breakdown of protein substances and to retarded renal elimination. It is recalled that severe disturbance of renal function, indicated by oliguria and by albumin, bile, debris, casts and erythrocytes in the urine, frequently accompanies shock (Eppinger⁶).

An increase in the hydrogen ion concentration and a decrease in the carbon dioxide-combining power of the plasma have long been recognized as regular features. These were considered etiologic until the results of experimentation showed them to be effects rather than causes.

Hypochloremia, chiefly a diminution of the level of sodium chloride, has been shown to accompany the increased nonprotein nitrogen content and decreased alkaline reserve mentioned previously. Scudder¹⁴ has shown that the blood sodium content is decreased in shock from various causes. His summary on changes in the blood indicated also that the potassium, calcium and magnesium contents are increased and that the amount of phosphates is decreased.

Isolated reports have indicated that the alkaline reserve is decreased and the chloride levels increased after hemorrhages. Scudder's data indicated that the blood potassium level is elevated during the moribund state resulting from loss of blood. Leichsenring and Biester's¹⁵ studies on the effects of hemorrhages in dogs showed a decrease in the nonprotein nitrogen level on the first day after the hemorrhages in eight of ten tests and a slight increase in two tests. They said: "The nonprotein nitrogen level per unit volume was slightly below normal during the postbleeding period." They cited reports of somewhat variable results by other workers and regarded the changes in the nonprotein nitrogen level after the loss of blood as transitory.

We undertook a comparison of the chemical and other hematologic changes which occur during shock and after hemorrhages. In the earlier tests, data on the

blood of dogs at or immediately before death were compared with data on the same dogs before the experiments. Then it was realized that values derived from moribund animals are not so reliable and may show variations not present before the animals were in a dying condition. In order to obviate this source of error in subsequent experiments, blood was drawn for examination when hemoconcentration or hemodilution indicated that the circulation was seriously affected by shock or by hemorrhage respectively. When a continuous record of the blood pressure was made, blood for chemical tests was drawn when the pressure had declined to a critical level of 70 mm. of mercury. In

A comparison of these data indicates that hemoconcentration, as shown by erythrocyte counts and hemoglobin and specific gravity readings, occurred regularly during shock and that hemodilution resulted after bleedings.

There was a noticeable increase in the nonprotein nitrogen content during shock in each instance; a moderate decrease was found in 4 of 6 dogs after hemorrhages. In 2 there was a slight increase.

The chloride content of the plasma declined moderately in 5 of 7 dogs during shock; in 2 there was no significant change. The level of chlorides increased in 5 of 6 dogs as a result of bleedings.

* Dogs 372, 373 and 375 were under amytal anesthesia during part of the experiment.

4 dogs shock was induced by absorption of muscle pulp from the peritoneal cavity, in 2 by repeated subcutaneous injections of histamine and in 1 by anaphylaxis (from horse serum). The data from these comparisons are shown in tables 5 and 6.¹⁶

16. Chemical determinations of the blood or blood serum were made according to the following methods: the Koch and McMeekin for non-protein nitrogen, the Folin and Wu for sugar, the Whitehorn for chlorides, the Peters and Van Slyke for carbon dioxide content and the Looney and Walsh for total protein. Descriptions of these methods may be found in:

- Koch, F. C., and McMeekin, T. L.: A New Direct Nesslerization Micro-Kjeldahl Method and a Modification of the Nessler-Folin Reagent for Ammonia, *J. Am. Chem. Soc.* **46**: 2066 (Sept. 5) 1924.
Folin, O., and Wu, H.: A System of Blood Analysis: I. A Simplified and Improved Method for Determination of Sugar, *J. Biol. Chem.* **41**: 367, 1920.
Whitehorn, J. C.: Simplified Method for Determination of Chlorides in Blood or Plasma (Supplement to Folin's System of Blood Analysis), *J. Biol. Chem.* **45**: 449, 1921.
Peters, J. P., and Van Slyke, D. D.: Quantitative Clinical Chemistry, Baltimore, Williams & Wilkins Company, 1932, vol. 2, pp. 245-251.
Looney, J. M., and Walsh, A. I.: The Determination of Globulin and Albumin in Blood Serum by the Photoelectric Colorimeter, *J. Biol. Chem.* **130**: 635 (Oct.) 1939.

There was an appreciable decline in the content of serum proteins per hundred cubic centimeters and in the carbon dioxide content of the plasma both in shock and after hemorrhage. The blood sugar content varied irregularly during shock, but a considerable increase occurred regularly after hemorrhage. Hence total proteins, blood sugar and reserve alkalinity are not points of distinction between shock and hemorrhage.

COMMENT

Several workers¹⁷ reduced the blood pressure of dogs below 70 mm. of mercury by the repeated withdrawal of blood from the femoral artery. When the arterial pressure sank, blood was introduced by direct transfusion;

17. Blalock, Alfred: Principles of Surgical Care, Shock and Other Problems, St. Louis, C. V. Mosby Company, 1940.
Freeman, N. E.; Shaffer, S. A.; Schechter, A. E., and Holling, H. E.: The Effect of Total Sympathectomy on the Occurrence of Shock from Hemorrhage, *J. Clin. Investigation* **17**: 359 (May) 1938.

when it rose above 70 mm., a quantity of blood was again removed. By this combination of removal and reintroduction of blood, the pressure was maintained at about 70 mm. for several hours. The animals showed a number of the clinical features of shock: weakness, pallor, thready pulse and low blood pressure. Hemo-

TABLE 7.—Items Identical in the Two Conditions

Sympathoadrenal activity
Stimulation of myocardium
*Strong, rapid pulse in early stages
*Peripheral vasoconstriction
Reduced volume flow
*Peripheral ischemia, pallor
*Loss of tissue turgor
Discharge of reservoir blood into systemic circulation
*Contraction of spleen
*Increased blood sugar content
*Dilatation of pupils, often perspiration
Low basal metabolism
*Declining temperature
*Decreased alkaline reserve
*Decreased serum protein content
*Increased respiratory rate, thirst
*Low arterial blood pressure (in late stages)
*Death due to inadequate circulatory function

concentration was observed in all such experiments. "Particularly impressive is the finding that all animals died despite the fact that more blood was introduced than had been removed." In other words, transfusion was without benefit after low blood pressure had existed for an extended period. Examination of the tissues after death showed visceral congestion, edema and petechial hemorrhages. "These observations prove that shock can be produced by uncomplicated hemorrhage and that hemoconcentration, a negative response to transfusion and alterations in the tissues result if the circulation remains depressed for several hours."

Before accepting these deductions in toto, one should examine thoughtfully the conditions of the experiments. It is known that neither man nor animals can survive when the arterial pressure is maintained, by whatever means, below the "critical level," i. e. 70 to 80 mm. of mercury.

Certainly when the blood pressure is maintained at 70 mm. continuously by hemorrhage or by any other means a point will be reached after which neither transfusion nor any other procedure will restore circulatory efficiency. Animals so treated inevitably die. When an animal is dying from any cause there is relaxation of vascular tonus affecting particularly the capillaries and venules. Anoxia, which regularly accompanies the moribund state, causes abnormal permeability of the endothelium. If at this stage a quantity of blood is introduced it will distend the atonic vessels and will produce visceral congestion. If death does not occur immediately, leakage of plasma will cause both edema and hemoconcentration.

If transfusions of blood were given to a dog moribund from some natural cause, such as neoplasm, infection with worms or nephritis, the same results would be expected to follow. Would the negative response to transfusions, unremitting decline in blood pressure, visceral congestion, edema and hemoconcentration indicate that neoplasm or other disease caused shock?

Other readers may interpret such results as the artificial production of the features mentioned and as a demonstration that vascular atony and endothelial permeability occur whenever an animal is moribund.

We have been unable to demonstrate hemoconcentration and the visceral pathologic changes of shock in animals brought to death by repeated losses of blood.

Nevertheless, we believe that capillary atony and endothelial permeability develop as terminal events when an animal is moribund from hemorrhages or from any other cause. These changes are accompanied by a grave derangement of fluid balance.

A highly important difference between shock and the effects of hemorrhages, as we see it, is that endothelial injury and the resulting disturbances of circulation and of fluid balance occur as initial derangements causing shock, while the same disturbances develop only in the terminal or moribund state after hemorrhages.

SUMMARY

Several features in the syndrome of shock occur also after hemorrhage because the two evoke the same physiologic mechanism for counteracting the disturbance. The points of resemblance are arranged in table 7. The items which we have verified experimentally are marked with an asterisk.

Incipient circulatory deficiency from shock, hemorrhage or other causes evokes compensatory reactions by the sympathoadrenal system resulting in identical responses. Hence no distinctions from the effects of hemorrhage were evident, and the two conditions were regarded as identical.

We have assembled the various physiologic and biochemical features which have been reported in cases of shock from wounds, burns, intestinal obstruction, anaphylaxis and other causes and reports on the same items as observed after uncomplicated hemorrhage.

TABLE 8.—Comparison of Results of Hemorrhage and Shock

Items	Shock	Hemorrhage
*Endothelium.....	Permeable to colloids	Impermeable to colloids
*Flow of lymph.....	Increased	Decreased
*Tissue fluid.....	Increased	Decreased
*Fluid balance.....	Disturbed	Undisturbed
*Pulmonary edema.....	Frequent	Absent
*Absorption from gastrointestinal tract	Impaired	Unimpaired
*Absorption from tissues....	Impaired	Unimpaired
*Vomiting.....	Persistent	No vomiting
*Diarrhea.....	Frequent	Absent
*Effect of moderate loss of blood	Severe	Mild
Transfusion of blood.....	Often ineffective	Effective
*Saline solution, administered intravenously	Ineffective	Often effective
*Urine.....	Concentrated, low volume; contains albumin, erythrocytes, bile and debris	No characteristic changes
Blood		
*Coagulation time.....	Lengthened	Shortened
*Hemoglobin content, erythrocyte count	Increased	Decreased
*Specific gravity.....	Increased	Decreased
*Nonprotein nitrogen level..	Increased	Decreased
Potassium content.....	Increased	Terminal increase
Calcium content.....	Increased	Decreased
Magnesium content.....	Increased	Decreased
*Chloride content.....	Decreased	Increased
Changes Seen at Necropsy		
*Edema of soft tissues.....	Characteristic	None
*Serous effusions.....	Present	Absent
*Capillovenous congestion..	Characteristic	Absent
*Petechiae.....	Characteristic	Absent
*Visceral ischemia.....	Absent	Present
Weight of organs.....	Increased	Decreased
*Gastrointestinal tract.....	Dilated, atonic	Contracted
*Parenchymal necroses.....	Present	Absent

These have been arranged in table 8 to facilitate comparison. We have verified experimentally the items marked with an asterisk.

Medical history records instances in which a symptom complex, once regarded as a disease entity, later has been shown to comprise several more or less unrelated conditions. The terms leprosy and Hodgkin's disease originally were applied to groups of conditions

having clinical resemblances but later shown not to be identical. Few terms have been used more loosely and indefinitely than shock. Hence it is not strange that the effects of hemorrhage, which clinically resemble shock so closely, should have been included without discrimination in the broad application of that term.

It is remarkable that numerous important differences so long have escaped the attention of persons interested in these conditions. We humbly admit our own error in subscribing for a time to the belief that uncomplicated hemorrhage will produce the syndrome of shock.

Since this article was written, Price¹⁸ and his associates have published the effects of simple hemorrhages as observed in 37 dogs. Their results confirm those which we have recorded. The interval between the first bleeding and the death of the animals ranged between five and six hours. Hemodilution occurred regularly; the clotting time was reduced; the plasma chlorides and sodium increased; the potassium and the nonprotein nitrogen of the blood rose shortly before death. Necropsy showed pallor of the tissues and organs. No edema nor increased wetness of the tissues, no abnormal fluid in serous cavities, no visceral congestion nor evidence of increased capillary permeability was seen. They concluded that "Evidence is presented to show that capillary atony, 'stasis' and abnormal permeability of capillaries probably do not occur in dogs following uncomplicated acute hemorrhage."

CONCLUSIONS

Points of similarity between shock and the effects of hemorrhage result in part from the fact that each evokes the same mechanism of compensation and in part from the deficiency of circulation which each produces.

Points of contrast between shock and the effects of hemorrhage are so numerous that the assumed identity of those conditions is no longer tenable.

Hemorrhage when present is a highly important contributory factor because the derangement of fluid balance which accompanies shock interrupts the processes by which loss of blood is compensated.

For the sake of accuracy the expression shock and hemorrhage should be substituted for the term hemorrhagic shock.

We urge investigators not to employ hemorrhage as a means for producing shock experimentally. If the results so obtained are interpreted as applying to shock, erroneous conclusions may be drawn.

1025 Walnut Street.

ABSTRACT OF DISCUSSION

DR. HENRY H. HARKINS, Detroit: Dr. Moon and I represent almost opposite extremes of belief concerning the mechanism of shock, especially concerning the particular aspect that Dr. Moon and his co-workers have presented today. One of the differences between our views is: Are hemorrhage and shock the same? At no time have I stated that hemorrhage is the same as shock, but I do believe that hemorrhage will lead to shock. Dr. Moon states that transfusions are effective in hemorrhage but not in shock. My work and that of Dr. Blalock and others have led to a contrary conclusion, namely that, if the hemorrhage is allowed to continue long enough, the restitution of even more blood than was removed will not restore the animal or patient. I am sure all of you have had experience with instances of severe bleeding that come in late and where large blood transfusions are given (probably larger than the amount of blood that was lost) and yet the patient does not recover. In the authors' chart where they discussed 26 dogs

with protracted hemorrhage so that the dogs did not die for a long period, I should like to know whether or not he had blood pressure readings. Several authors have found that pathologically the changes in protracted hemorrhage are much the same as in protracted shock. However, it is essential that the blood pressure remain low for several hours if hemorrhage is to cause these pathologic changes. In such cases the pathologic changes at autopsy will be much the same whether the shock was produced by hemorrhage or by other injury, as shown by Blalock of Johns Hopkins, the late Mr. O'Shaughnessy of London, and more recently by Dunphy, Gibson and Keeley. From the practical point of view, especially when we are approaching war, it should be pointed out that, even if shock produced by other means differs somewhat from shock produced by hemorrhage, too much importance should not be attributed to this from the point of view of treatment. Since we do not know about some of the obscure manifestations of shock and our chief means of treatment is to give fluid replacement, whether the fluid lost is whole blood or plasma, the most important item is to restore it as quickly as possible. If a patient has hemorrhage plus other types of shock there may not be hemoconcentration. Some of my recent work not yet completed has shown that in shock a great deal of fluid is lost remote from the site of injury, in agreement with the work of Moon and his collaborators.

THE SURGICAL TREATMENT OF PROSTATIC DISEASE

ROY B. HENLINE, M.D.

NEW YORK

Surgical diseases of the prostate gland present so many variations that no one surgical procedure will obtain the best results in all cases. A thorough understanding of the site of origin and progression of the disease permits one to select the proper surgical approach in each instance. So commonly do surgeons refer to the various types of prostatic operations as "removal of the prostate" that many forget that the prostate is rarely actually removed. In many instances only the hyperplastic tissue, or so-called adenoma, is removed; the functioning prostatic glands or their remnants remain firmly attached to the surrounding fascia and together are referred to as the false capsule of the prostate. Often removal of this hyperplastic tissue is all that is required to establish adequate drainage of the bladder, and the remaining compressed, uninvolved prostatic tissue may reasonably be left behind. It is not uncommon, however, for these remaining prostatic glands or their remnants to be the seat of a pathologic process which also requires removal for the patient to be cured.

ETIOLOGY

There is evidence that hyperplasia (adenoma) of the prostate in advancing years is incited by an imbalance of male and female hormones. As yet, however, there is no pathologic evidence that hormonal therapy will inhibit or stop this process once it has begun.

Just which elements in the prostate give rise to prostatic hyperplasia has been a much discussed subject for years, although observers have agreed that the new growth makes its first appearance near the urethra and just under the mucosa. Tandler and Zuckerkandl,¹

Read before the Section on Urology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

The expenses of this research were defrayed from the Alfred P. Sloan Research Fund of the Foundation of the

among others, expressed the belief that prostatic hyperplasia develops from the short prostatic glands which extend only a short distance beneath the mucosa in the prostatic portion of the urethra (fig. 1). This is the locality where hyperplastic changes are first seen in the prostate. Deming and Wolf,² in a recent study of 210 prostates, agreed with these authors regarding the location of the new growth but claimed that hyperplasia does not arise directly from these short prostatic glands, being first seen as a fibromuscular mass in the muscular wall of the prostatic portion of the urethra. Deming³ suggested that this mass may correspond to uterine myoma, since theoretically the two growths have a common embryologic anlage. The fibromuscular masses lie parallel to the muscular fibers of the urethra between the prostatic ducts and stimulate epithelial hyperplasia from these ducts of the prostatic glands (fig. 2). Deming and Wolf stated that this hyperplasia is not an enlargement of existing prostatic glands but, although similar in structure, is composed of newly formed glandular elements from the ducts of the prostatic glands. This explains its locality surrounding the prostatic urethra, from which the growth extends to compress the true lateral and posterior lobes toward the capsule and hence assumes the position of the lateral lobes on each side of the urethra (figs. 3 and 4).

Hyperplasia of the prostate may occur just under the urethral mucosa in the region of the lateral lobes, the median commissural lobe, the subcervical lobes or the subtrigonal lobes (fig. 5). However, it does not occur in the posterior lobe of the prostate, nor does it originate in the functioning glands of the lateral or median prostatic lobes. As the hyperplasia in the region of the lateral lobes increases in size, the prostatic portion of the urethra is distorted with an anteroposterior elongation (figs. 3 and 4). Eventually the urethra is so compressed as to cause urinary retention.

Since the ducts of the prostatic glands are involved in this hyperplasia, the drainage from these glands into the prostatic portion of the urethra is gradually obstructed. If the glands are infected, a walled-off focus of infection may remain in the compressed remnants of the prostate gland.

Fig. 1.—Prostatic hyperplasia develops near the urethra, as shown diagrammatically by the encircled dotted line. The external glands, or prostatic glands proper, are compressed toward the capsule as the hyperplastic mass increases in size. The posterior lobe is not shown but is in the region marked "ejaculatory ducts."

PROSTATIC CALCULI

The entire prostate undergoes a change at the age of about 50. R. A. Moore⁴ has shown how poor drainage from the prostatic glands predisposes to the

formation of a nucleus of desquamated epithelium and debris to form corpora amylacea. These foreign bodies are formed in the functioning prostatic glands in contradistinction to the hyperplasia, which develops near the urethra from the gland ducts. The corpora amylacea are frequently surrounded by round cell infiltration and

Fig. 2.—Cross section ($\times 2$) of prostate of a man aged 74 showing nodule (N) one half of which is glandular and the other half aglandular. Note fibromuscular masses on each side of the urethra being invaded by epithelial hyperplasia from the ducts of the prostatic gland. Note beginning compression of the lateral lobes (L. L.) by this mass and the uninvolved posterior lobe (P. L.). (From Deming.)

fibrosis in the prostatic gland itself. Calcium salts may be deposited around these nuclei to form prostatic calculi.

Corpora amylacea, or prostatic calculi, often surrounded by evidence of infection, may be present for years without causing any symptoms. In some patients, however, a severe infection develops and symptoms are produced that require surgical intervention. In other patients hyperplasia (adenoma) may develop in the region of the ducts near the urethra. As this increases in size the corpora amylacea, infection and calculi if present are compressed toward the capsule with the prostatic glands; the ducts from the prostatic glands are gradually occluded, and the infected prostatic remnants may no longer drain into the urethra. Some glands become atrophic, while in others infection or calculi may be walled off by the enlarging hyperplasia (fig. 6).

CARCINOMA

Carcinoma of the prostate is said to originate in the posterior lobe in about 75 per cent of cases. Recent statistics by Moore⁵ and Rich⁶ drew attention to the fact that between 14 and 16 per cent of all men over 50 have prostatic carcinoma. Although these percentages seem rather high, carcinoma of the prostate either is becoming more common or is being recognized more frequently. In treating prostatic disease one cannot overlook these observations without giving serious thought to rational treatment. Since the average life expectancy of men has increased, it may be that one should expect to find prostatic malignant neoplasms more frequently.

DIAGNOSIS

The exact nature and extent of prostatic disease should be determined before the type of surgical procedure to be employed is decided on. Frequent urina-

tion and the finding of residual urine in the bladder and of an enlarged prostate by rectal examination are not sufficient evidence to suggest the employment of a particular type of surgical procedure. Rectal examination, though valuable, may be misleading in the diagnosis of the presence or the extent of prostatic disease in almost 50 per cent of cases.⁷ It is not uncommon

Fig. 3.—Cross section (under low power) of an entire prostate gland, showing multiple adenoma in neighborhood of urethra. Periphery shows nonadenomatous prostatic tissue. Note the replacement of the fibromuscular mass by hyperplasia, which is assuming the position of the lateral lobes. The lateral and posterior lobes are further compressed and are becoming functionless. Between the hyperplasia and the compressed lateral lobes is the "line of cleavage" where "enucleation" of the prostate by suprapubic or transurethral prostatectomy is performed, the remnants of prostate left behind being called the false capsule. (From Geraghty.)

to have a patient who has been referred by a physician state that rectal examination has ruled out prostatic disease, only to find that the prostate is actually the source of his symptoms. Hyperplasia of the subcervical or subtrigonal lobes or of the median commissural lobe and the presence of fibrous bars at the vesical outlet are among the conditions which may cause no change in the contour or size of the prostate as revealed by rectal palpation yet may require surgical intervention for their relief.

The exact location and extent of the obstruction should be established. The presence of prostatic infection, fibrosis or calculi should be determined. Cystoscopic examination when indicated will aid the urologist in selecting the type of operation in many instances. The presence of a hard nodule in the prostate determined by rectal palpation is suggestive of a malignant neoplasm, and the nodule should be treated as such until proved otherwise.⁸ Considerable information concerning the size and extent of the prostatic obstruction may be obtained by an aerogram and cystourethrogram, with the patient in a semilateral position. In most instances the procedure may be performed with little discomfort to the patient.⁹

TREATMENT

When the exact diagnosis of the type of prostatic disease has been established, one must decide on the surgical procedure which will relieve the patient promptly and permanently. The origin and location of the disease and its underlying pathologic changes

should be considered, since a clear understanding of the progression of the disease is often the deciding factor between one approach and another. To attempt to remove a fibrous prostate, particularly if calculi are present, by suprapubic prostatectomy reveals poor surgical judgment. One cannot remove the posterior lobe of a prostate containing an early malignant neoplasm by suprapubic prostatic enucleation.

The particular method used for removal of the prostate has, in the past, depended to a large degree on the choice of the surgeon, who has considered only his training and ability to relieve the obstruction. In some instances he has overlooked the underlying pathologic condition and has not selected the operation most likely to give the patient complete and permanent relief from his prostatic disease. In other words, the surgical procedure employed should depend, not on the surgeon's skill with any one method, but on the nature of the pathologic process in the prostate.¹⁰

It is essential that renal damage, infection and hemorrhage and retention of urine be considered in the treatment of all patients with prostatic disease. These conditions have been thoroughly discussed in the literature. One finds statistics showing a low mortality for each type of surgical approach to the prostate, and one is aware that the low mortality is the result of the proper preparation of patients by a surgeon who is highly skilled in the surgical approach he advocates. With the same patients and a surgeon skilled in a different surgical approach to the prostate, a similar mortality would probably result.

In some patients who have had a suprapubic enucleation of the prostate or a transurethral resection, a postoperative morbidity persists, with infected urine and frequent urination. These symptoms are distressing both to the surgeon and to the patient. Sometimes they result from infection in the remnants of the prostatic tissue or the seminal vesicles and might have been prevented by removal through the perineum of the prostatic capsule and prostatic remnants together with the hyperplasia.

Transurethral removal of obstructing hyperplastic tissue from the prostate is a rational procedure and has assumed an important place in prostatic surgery. With proper selection of cases and a skilled surgeon, excellent results can be obtained. Opinions vary as to the size of the prostate which is best treated by transurethral operation. However, with a surgeon properly skilled in this procedure, relatively large hyperplastic masses may be adequately removed. Some surgeons prefer to remove large intravesical prostatic hyperplastic masses suprapubically, and similar results may be obtained with these growths by either method.

Fig. 4.—Cross section of prostate removed by subtotal perineal prostatectomy. Note progression of hyperplasia and further compression of functioning prostatic glands, which now have become the false capsule. Enucleation would not remove these prostatic remnants. The line of cleavage between the hyperplasia and the compressed prostatic remnants is clearly visualized.

When it becomes desirable to remove the remnants of the functioning prostatic glands because of infection, calculi or a hard nodule in the prostate suggestive of a malignant neoplasm, it is essential to approach the prostate by the perineum.¹¹ Neither by the transurethral nor by the suprapubic approach is it possible to remove either these prostatic remnants or the posterior

Fig. 5.—Localities where hyperplasia may develop

lobe of the prostate. The posterior lobe and the false prostatic capsule are separated from the hyperplastic mass in the prostate by a line of cleavage which permits the hyperplastic tissue to be cleanly "shelled out" suprapubically (fig. 3). The remnants of the prostate, in which it is estimated that 75 per cent of carcinoma develops (posterior lobe), must of necessity be left behind in either a suprapubic enucleation or a transurethral resection.

SUBTOTAL PERINEAL PROSTATECTOMY

New perineal operations have recently been devised.¹² Among these is a subtotal perineal prostatectomy devised by me primarily for the complete removal of prostatic calculi.¹¹ Results with this procedure have been so satisfactory that its use has been extended to the treatment of severe prostatic infection with hyperplasia, prostatic fibrosis in some cases, all early malignant neoplasms and extensive hyperplasia of the lateral lobe in some cases.

The method consists in the usual perineal exposure and removal of the entire prostate, capsule and prostatic portions of the urethra. Hemorrhage is controlled by sutures. The distal portion of the urethra is sutured around a catheter to the neck of the bladder and the prostatic portion of the urethra is thus entirely eliminated.¹¹

By this subtotal method¹³ the obstructing tissue as well as all remnants of compressed prostatic tissue may be completely removed. No focus of infection remains in the prostatic portion of the urethra to cause persistent urinary symptoms. The posterior prostatic lobe is removed, and hence a possible source of undiagnosed malignant growth is eliminated. The patient should be told that temporary or even permanent sexual impotence may result from this procedure.

When a suspiciously hard nodule is palpated in the prostate on rectal examination a perineal exposure, with complete removal of the prostate, offers the only hope

of cure should the growth prove to be early carcinoma of the prostate. The posterior lobe of the prostate can be reached only by the perineal approach, and the patient deserves to be operated on by the method which offers him a hope of cure. When it is considered that 1 of every 5 to 7 patients past the age of 50 has carcinoma of the prostate, is one not justified in removing the posterior lobe of the prostate, together with the obstructing portion of the gland, when the condition is suspected? Other methods of treating prostatic carcinoma are rarely curative and offer only relief from symptoms.

It is my custom to expose the prostate by opening the perineum when a suspicious nodule has been palpated. A small section of the suspected area is removed and a frozen section made at once. If carcinoma is discovered a radical perineal prostatectomy is performed, the entire prostatic portion of the urethra and the seminal vesicles being included. If biopsy proves the growth benign, either a conservative prostatectomy is performed, if indicated, or the perineum is closed. Exposure of the prostate by opening the perineum, with performance of biopsy, is far superior to repeated attempts to obtain a specimen with a needle through the perineum. A negative report on such a specimen proves nothing, since the involved area may be small and easily missed. In a recent case, taking a small biopsy by perineal exposure of the prostate removed the entire malignant area, and careful microscopic examination of the rest of the prostate and the seminal vesicles failed to reveal any sign of malignancy.

Since cancer of the prostate is so common, and until such time as conservative treatment of prostatic carcinoma proves more satisfactory as to cure and the prevention of the subsequent suffering, it may not be unreasonable to consider the advisability of removing the posterior prostatic lobe and capsule when surgical intervention must be instituted anyway for obstruction. Although I do not recommend this procedure routinely, the conclusions drawn from statistics may force the

Fig. 6—Prostatic calculi. Note the presence of calculi throughout the functioning prostatic glands, extending to the outside surface of the capsule.

consideration of it in the future if patients are to be offered the best outlook for continued health.

I am opposed to the pessimism frequently voiced regarding carcinoma of the prostate. For a physician to palpate a suspiciously hard nodule in the prostate and "wait" to see what happens is a violation of the trust placed in him. It is only patients with such nodules that one can hope to cure of this disease, and

13. "Subtotal method" refers to removal of the entire prostate with the capsule and all prostatic tissue and is distinguished from radical total prostatectomy since the seminal vesicles are allowed to remain intact.

unfortunately most of them have no urinary symptoms! In the greater number of cases of prostatic carcinoma, when extension has occurred transurethral resection or perineal prostatectomy offers relief from urinary retention, and high voltage therapy often relieves the pain from metastases.

CONCLUSION

In conclusion, may I repeat that only the hyperplastic or fibrous mass may be removed by suprapubic "prostatectomy" or by transurethral resection. To enable one actually to remove the prostate gland, a perineal exposure is necessary. Only by perineum can the posterior lobe (the site of 75 per cent of malignant neoplasms of the prostate) be removed together with the compressed remnants of the functioning prostatic glands. Only by maintaining a clear conception of the various pathologic lesions which may involve the prostate and after proper study should one decide on the rational surgical procedure in each case. To treat all types of surgical prostatic disease by one method is not sound from a pathologic viewpoint. Surgeons are rightly considered inadequate if through lack of preliminary investigation, study and understanding of the pathologic process present they fail to approach the problem by the method particularly fitted to give adequate permanent relief.

SUMMARY

1. Each of the three main types of prostatic operation has its place, yet none should be used to the exclusion of the others.

2. The origin, extent and location of prostatic disease should always be considered in selecting the proper surgical approach to relieve the patient completely and permanently from his prostatic disorder.

3. Prostatic calculi may be more completely removed by subtotal perineal prostatectomy, with less morbidity and more permanent cure.

4. Perineal exposure, with removal of the posterior lobe of the prostate, is the only method of adequately removing an early malignant neoplasm of this portion of the prostate.

5. Newer perineal prostatic operations permit adequate control of hemorrhage and offer a means of completely removing the diseased prostate, often preventing postoperative morbidity, with greater assurance of permanent lasting relief from prostatism.

ABSTRACT OF DISCUSSION

DR. HERMON C. BUMPUS JR., Pasadena, Calif.: Many years ago Dr. Geraghty reviewed a series of cases of cancer of the prostate and found the posterior lobe to be the most frequent site of malignancy. Not so long ago, Kahler examined by serial section over 400 glands and found the lateral lobes more frequently involved than the posterior lobes. The gist of Dr. Henline's paper is that, as every fifth patient with prostatism presumably has a malignant condition present, one is not justified in doing other than a perineal prostatectomy for fear the malignant condition may invade the posterior lobe. Perineal surgery is a highly technical procedure taught in relatively few clinics. How can the average surgeon expect to master this technic and at the same time acquire the more involved and difficult one of transurethral resection? However, all who have been trained in the fundamentals of surgery can do a suprapubic prostatectomy. This might seem deplorable if it did in fact deprive every fifth prostatic patient of a cure of his disease and statistics showed that perineal prostatectomy actually cured any appreciable number of cases. Such, unfortunately, is not the case, owing to the fact that the perineal lymphatics of the prostate drain directly into the sacrum. Careful pathologic investi-

gation has shown that there is no relationship between the extent of the malignant growth and the involvement of these perineal lymphatics. As a result, the early discovery of this disease means little as far as the chances of its cure are concerned but a great deal as far as the duration of the disease is concerned, for there are numerous untreated patients, except for the relief of their obstruction, who have lived over a decade from the time of its discovery. It is to be regretted that our literature does not contain reports of any series of patients treated by the perineal prostatectomy in which a sufficient number lived even over a five year period to make one certain that their survival was not due as much to the relief of their obstruction and the natural slow progress of the disease as to the eradication of the malignant growth. With few exceptions, urologists are far from satisfied with their end results in the treatment of prostatic cancer. In the great majority of cases relief of obstruction is what prolongs life, and our final results depend on the completeness with which this is done.

DR. CHARLES C. HIGGINS, Cleveland: Dr. Henline's initial sentences are of prime importance. Surgical diseases of the prostate present so many variations that any one surgical procedure will fail to obtain the best results in all cases. Patients enter the hospital with acute obstruction who cannot have a catheter introduced into the bladder, and a suprapubic puncture or cystostomy must be done. Some of these patients can have the resectoscope introduced after preliminary drainage, but others cannot. Another group of patients are those with complete retention in which futile attempts to catheterize and evacuate the urine have been made. Metal sounds have been passed, the urethra has been torn, the penis is swollen, and the patient may have urethritis or unilateral or bilateral epididymitis. In these instances I would hesitate to perform a transurethral resection. A third group are patients with carcinoma of the prostate. I agree with Dr. Bumpus in that, when it is impossible to remove the malignant disease surgically in a very large prostate, transurethral resection is preferred. The fact must be appreciated that at some time the malignant lesion in the prostate was a local disease. Therefore, if a small nodule is palpated in a man aged 50, regardless of whether or not he has residual urine, one is justified in exposing the prostate by the perineal approach, securing a biopsy. If it is not malignant and merely an adenoma, the incision can be closed; if it is malignant, a radical procedure can be undertaken. The morbidity is much less in suprapubic prostatectomy, but personal preference also influences the choice of operation. The patients who present some discussion are those with grade 3 and grade 4 enlargements of the prostate. A sufficient amount of prostatic tissue can be removed to provide the patient an adequate channel so that he can entirely empty his bladder. However, many of these patients have a persistent pyuria which does not clear up until the prostate is removed. Microscopic examination of this prostatic tissue shows numerous infarcts and multiple abscesses. In the majority of instances it is not necessary to have an intensive preoperative regimen for patients who undergo transurethral surgery, provided there are no complications. However, the complications that may occur following operation must be anticipated. I have seen postoperative hemorrhage after transurethral resection. The patient loses large amounts of blood, which necessitates taking the patient to the operating room, evacuating the clots from the bladder and again introducing the resectoscope to control the bleeding point. Occasionally, postoperative pneumonia will develop. If that patient's preoperative routine has been minimized, a higher operative mortality may be anticipated.

DR. FRANKLIN FARMAN, Los Angeles: I should like to present a somewhat different approach to the problem of prostatic surgery. Most indications for surgery are based on the anatomicopathologic picture found at the bladder neck; however, as a rule only the doctor himself understands this setup. In talking to patients I have found the following outline useful: most people place themselves in certain age groups and likewise does the "prostatic": From 50 to 60, resection or endocrine therapy; from 60 to 70, resection or one stage prostatectomy; from 70 to 80, two stage prostatectomy or resection; from 80 to 90, fractional resection, delayed two stage, permanent cystostomy, "catheter life." Between the ages of 50 and 60 one

encounters more frequently early benign adenoma, fibrous bar or commissural hypertrophy alone, and for these patients resection is ideally suited, mortality is nil and the functional result is good. At this stage, endocrine treatment (testosterone) is being tried with moderately encouraging results, and it is my belief that the field for glandular replacement therapy is greatest in the incipient stages of prostatic disease. Between the ages of 60 and 70, more extensive benign prostate enlargements and early carcinoma make their appearance. Life expectancy is fully ten years, and any contemplated surgery should keep this in mind, so as to insure the patient complete relief thereafter. Does resection always do this? During the past winter I have seen 5 patients on whom resection has been performed by five different doctors in the Midwest, all with recurrence of bladder difficulty, hematuria, stricture or infected residual urine. As the later decades of life are reached, complications are more frequent, operative hazard is increased and differentiation of cases becomes more necessary. In the age group 70 to 80, grade 3 and 4 benign adenoma, frank carcinoma, acute and long standing retention, urinary infection and lithiasis, damaged kidney function, arteriosclerosis, myocarditis and hypertension are factors of greater or lesser significance. Life expectancy is correspondingly shortened. The choice of method here has great influence on mortality and morbidity and depends on personal skill, available hospital equipment and assistance, the locality in which the patient resides and the objective in treatment—relief of symptoms or cure. Although the mortality rate is somewhat higher for total prostatectomy than for resection in this group, morbidity figures generally are lower. Paradoxical as it sounds, resection is advocated by some for both the "good risk" and the "poor risk" patient. This is true to a certain extent when considering the last age group beyond 80 years. Life expectancy is short and palliative relief usually is the objective, which may be accomplished by partial or fractional resection, delayed two stage, or permanent cystostomy.

DR. V. D. LESPINASSE, Chicago: Dr. Henline's paper is a plea to consider prostatic disease as a group of diseases, to consider it the same as we do intracranial, abdominal or pleural disease. There are many methods available and there are many different types of pathologic conditions that we need to relieve. Our methods of examination give us three aspects: (1) the intravesical aspect, (2) the perineal and (3) the urethral. Those methods will demonstrate the exact pathologic condition, and the problem is how best to get rid of that condition. If it is a small obstruction in the urethra there is no advantage, in fact it is foolish to do anything but a local urethral destruction. If there is a pathologic lesion in the bladder, it seems to me that the easiest and best way to remove it is to go into the bladder. If the pathologic process is on the rectal side of the prostate, then the most accessible way to get at it is through the perineum. If one studies the case better and considers the pathologic condition of the particular patient, one most certainly will obtain better results. As far as the various points of technic are concerned and the saying of *carte blanche* to do it above or below, I don't think that is profitable to discuss: For my own abilities I can do a total anatomic removal of the prostate suprapubically from the membranous urethra to the urethral orifices, unite the trigon of the bladder to the urethral orifice as it comes through the urogenital ligament, and wrap a few Wilson's muscles or the puboprostate ligament around it and obtain a nice result with little mortality. Patients are well pleased and their carcinoma is no longer in their body. Whatever way one works, one must pay attention to the pathologic lesion and remove it; then one will have some excellent results.

DR. ROY B. HENLINE, New York: Dr. Bumpus mentioned the pertinent fact that pathologists often disagree on the diagnosis of prostatic cancer. Various articles written on this subject tend to confuse the issue on the origin and progression of prostatic cancer. In my text I did not refer to Dr. Geraghty's original paper on prostatic cancer when I stated that approximately 75 per cent of these cancers originated in the posterior lobe of the prostate. I referred to two recent, very careful, investigations by Moore and Rich, who independently found the posterior lobe of the prostate to be the site of origin of approximately 75 per cent of prostatic cancers. As long as pathologists agree that most prostatic cancers originate in the posterior lobe,

we as urologists should treat our patients by that method which will adequately remove this involved area. Apparently Dr. Bumpus misunderstood one of my purposes in presenting this paper. For fear that others may have misunderstood I should like to reiterate that I am not recommending perineal prostatectomy to the exclusion of other types of surgery. The latest statistics show that perineal prostatectomies are performed in approximately 30 per cent of patients, transurethral resection in 60 per cent and suprapubic enucleation in 10 per cent. I believe that the type of surgery employed should depend on the pathologic condition present in the prostate. To attain this goal, perineal prostatectomy must be employed for some patients. Dr. Bumpus also stated that the technic of perineal surgery is difficult. I find it more difficult to teach the resident staff transurethral resection than perineal surgery. I believe that proper transurethral surgery is among the most difficult urologic procedures one has to perform. If Dr. Bumpus had done as many perineal prostatectomies as he has transurethral resections he would find that learning perineal surgery is much easier than learning transurethral surgery. If I have brought out no other point, I should like once more to stress that not all patients with prostatic disease should be treated by any one method.

INTRASPINAL THERAPY OF NEUROSYPHILIS

ROBERT R. KIERLAND, M.D.

AND

PAUL A. O'LEARY, M.D.

ROCHESTER, MINN.

A great number of articles in the literature from 1910 until the early 1930's attest the value of intraspinal methods in the treatment of neurosyphilis. However, since the advent and ensuing favor of various other measures, this method of therapy gradually has been discarded by many syphilotherapists and we think unjustifiably so.

In appraisal of the methods of treatment dealt with in three papers from the Cooperative Clinical Group,²⁷ it must be remembered that the various forms of supplemental therapy in general were used only after routine therapy had failed and many of the patients had more than one type of supplemental treatment. The conclusions that were reached in the aforementioned papers, therefore, do not constitute a true comparative evaluation of the symptoms of treatment but rather constitute contrast of one method with another when simpler methods failed to produce the desired clinical and serologic results. For example, a comparison of intraspinal therapy with routine treatment cannot be made on a numerical basis because intraspinal therapy was administered usually to patients whose condition was resistant and who had failed to improve under routine treatment. However, the three reports clearly indicate the value of intraspinal therapy in certain forms of neurosyphilis, especially in mild or early tabes dorsalis and in the asymptomatic, meningeal and meningovascular forms of neurosyphilis.

From the Section on Dermatology and Syphilology, Mayo Clinic.

Read before the Section on Dermatology and Syphilology at the Ninety-second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

Owing to lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

THEORIES OF THE MECHANISM OF ACTION OF INTRASPINAL THERAPY

There are essentially four theories concerning the mechanism of action of the various forms of intraspinal therapy. These are that:

1. The amount of arsenic introduced into contact with the cerebrospinal fluid, although small, has a definite antisymphilitic action.
2. As a result of the introduction of the foreign material there results an increased permeability of the meninges due to meningeal irritation, which increases the concentration in the cerebrospinal fluid of arsenic, bismuth and other antisymphilitic drugs administered intravenously or intramuscularly.
3. The antibodies which are brought forth in the blood as the result of the primary injection of arsphenamine are transferred in the serum to the cerebrospinal fluid.
4. There is a nonspecific protein effect produced by the introduction of the blood serum into the spinal canal.

It is probable that all these theories play more or less definite roles in the production of the good clinical and serologic results obtained from intraspinal therapy. However, it is not our intention to discuss in detail these theoretical considerations of the mechanism of action of intraspinal treatment or to evaluate other similar types of treatment, such as spinal drainage and cisternal drainage, although we have had some experience with such methods. The results to be given in this report deal only with the so-called Swift-Ellis type of intraspinal therapy. For several years, reinforcement of the blood serum with minute doses of arsphenamine according to the method of Ogilvie was carried out but was discontinued because the results did not warrant the additional hazard incurred by the method.

SCOPE OF THE STUDY

This survey is based on the study of 370 patients suffering from various types of neurosyphilis who had received a total of two thousand, three hundred and sixty-nine intraspinal treatments, an average of six and four-tenths treatments per patient. The largest number of treatments administered to one person was thirty-nine and the smallest number one. These patients were treated during the years 1924 through 1927 and were selected because of the opportunity thus presented for a prolonged follow-up study.

TECHNIC OF INTRASPINAL THERAPY

Twenty to thirty minutes after an intravenous injection of arsphenamine or neoarsphenamine, 50 cc. of blood is aseptically withdrawn into sterile containers. The blood is allowed to stand until the serum separates and the serum then is pipetted off into another sterile container of a capacity of approximately 50 cc. The remaining clotted blood and serum are centrifuged and the remaining serum is again pipetted. Usually, 20 to 25 cc. of serum is obtained. The serum is then stored in a refrigerator overnight and in the morning it is heated to 56 C. for seventy minutes to destroy the complement; it is then centrifuged again to separate the few erythrocytes that may be present. This must all be done by means of a rigidly strict sterile technic.

Lumbar puncture is then done in the usual manner (in the fourth or fifth lumbar interspace) and 20 to 25 cc. of cerebrospinal fluid is removed, of which 10 cc. is saved for the globulin, cell count, protein, colloidal gold and serologic determinations; the rest of the fluid is discarded. The blood serum is then added to a gravity tube and allowed to flow into the subdural space by gravity; no pressure or force of any type need be

employed when the serum is being introduced into the spinal canal. The patient is then kept in bed for twenty-four hours. The foot of the bed is elevated about 8 inches for six to eight hours and the patient is urged not to use a pillow for twelve to eighteen hours.

Each intraspinal treatment is administered at two week intervals and three such treatments are considered to constitute a course. During this six week period the neurosyphilitic patient also receives routine treatment in the form of an injection of arsphenamine once weekly, heavy metal (either mercury succinimide five times weekly or bismuth two or three times weekly) and potassium iodide by mouth or sodium iodide intravenously.

The patient who has cardiovascular syphilis and only coincidental neurosyphilis for whom the administration of arsphenamine is contraindicated may receive so-called foreign arsphenaminized serum with benefit. In this modification the arsphenamine is administered first to another syphilitic patient; blood is withdrawn from this patient and the serum is extracted in the usual manner. The arsphenaminized serum thus obtained is then administered intraspinally to the patient who has both cardiovascular syphilis and neurosyphilis.

REACTIONS

In the total number of two thousand three hundred and sixty-nine treatments there were two hundred and twenty-nine reactions in 109 patients of sufficient degree to warrant their having been recorded in clinic files, an incidence of 9.7 per cent. These reactions were classed as "slight," "moderate" or "severe";²⁸ there were ninety-three slight reactions (3.9 per cent of the total number of treatments), ninety moderate reactions (3.8 per cent) and forty-six so-called severe reactions (1.9 per cent).

It is interesting to note that 39 per cent of all reactions occurred in a small group of 18 patients, and in this group it was necessary to discontinue intraspinal therapy for only 1 patient, a tabetic patient in whom increasing ataxia developed after intraspinal treatment; and, although there was some question as to the part played by the treatment in the production of the ataxia, it nevertheless was included among the reactions.

Reactions occurred most frequently among the tabetic group of patients for whom therapy provoked increased pains in the leg and/or gastric crises of varying degrees. There were 8 patients among the entire group for whom it was necessary to discontinue intraspinal therapy because of the occurrence of reactions of one type or another.

The reactions noted most commonly were those referable to ordinary lumbar puncture and slight to severe headache, which may or may not have been associated with nausea and vomiting. Two hundred of two hundred and twenty-nine reactions constituted headache, nausea and vomiting and increased pains in the legs.

Among the severe complications was 1 instance of meningitis, from which the patient recovered within three weeks' time without residual difficulty. In 5 cases complications developed which were referable to the

28. Slight reaction: Symptoms of the type of headache which often follows lumbar puncture, increased pains in legs and mild degrees of nausea and vomiting lasting less than twenty-four hours. Moderate reaction: Reactions in this group sometimes endured up to forty-eight hours. Patients sometimes required periods of rest in bed and sedation. Symptoms were of the same general type as those which follow lumbar puncture. Severe reaction: Reactions of the severe type lasted for more than 48 hours and required rest in bed and sedation. Provocation of pains in legs and gastric crises by the Swift-Ellis treatment and the occurrence of meningitis also are included in this group.

bladder. Three of the patients who had vesical complication received additional intraspinal treatment without the recurrence of complications. For the other 2 patients additional Swift-Ellis treatment was not attempted. In 2 cases transverse myelitis developed after the use of intraspinal therapy; however, both of these patients recovered without evidence of residual neurologic effects and 1 was able to tolerate additional intraspinal therapy without subsequent disturbance. One patient manifested saddle anesthesia; however, he also was able to tolerate Swift-Ellis treatment later without any untoward reactions.

It is to be remembered that, during the twenty-four year period in which intraspinal therapy has been used in the clinic, more than twelve thousand such treatments have been administered and that complications such as meningitis, retention of urine and transverse myelitis have developed among patients other than those considered in this study. Such reactions, however, are uncommon, since in the present series of two thousand three hundred and sixty-nine consecutive intraspinal treatments administered during the years 1924 to 1927 only nine troublesome complications occurred.

RESULTS

The consecutively selected records in this study concern a group of 370 neurosyphilitic patients who received one to thirty-nine intraspinal treatments in conjunction with therapy with arsphenamine, neoarsphenamine or sulfarsphenamine and mercury or bismuth compounds and, in the majority of instances, with iodides. Two hundred of these patients were observed and/or treated for five years or longer. These 200 patients who have had treatment and have been observed for periods of five years or more form the basis of the clinical and serologic results to be described hereafter. For 178 of these 200 patients, treatment was started by a combination of routine and intraspinal therapy.

The various manifestations of neurosyphilis in this group were diagnosed as follows: asymptomatic, tabes dorsalis, the tabetic form of dementia paralytica, dementia paralytica, meningeal and meningovascular. There were only 2 cases of purely vascular neurosyphilis, and these have been included with the meningovascular group of cases of neurosyphilis and the tabetic form of dementia paralytica.

Asymptomatic Neurosyphilis.—Thirty-two patients (16 men and 16 women) had asymptomatic neurosyphilis; their ages varied from 5 to 50 years. Nine of these patients previously had received various degrees of intravenous and intramuscular antisyphilitic therapy²⁹ and in 4 of the 9 the reaction to serologic tests of the blood was negative when they came under our observation. With routine treatment, plus the addition of intraspinal therapy, the blood became normal for 24 additional patients. According to classification by types of cerebrospinal fluid encountered, 7 patients had group I spinal fluid, 22 had group II spinal fluid and 3 had group III spinal fluid. Explanation of the classification of the three types of spinal fluid may be found in table 1. Twenty-five patients obtained reversal of the condition of the spinal fluid by means of intraspinal and routine treatment alone. Reactions to tests

of the spinal fluid of 4 patients remained positive in spite of treatment, and in 3 patients reactions to such tests relapsed to positive.

Four patients received malaria therapy in addition to routine and intraspinal treatment. One of these 4 patients, because of previous intensive treatment before the patient was seen by us, received therapy with malaria fever first, and then routine and intraspinal treatment. The spinal fluid of this patient first became normal nine years after fever therapy. The second patient received fever therapy with malaria because the reactions of tests of the spinal fluid relapsed to positive, whereas the other 2 patients of this group of 4 received treatment with malaria because of persistently positive reactions to tests of the spinal fluid. Reactions to such tests in 1 of these 2 cases remained positive five years after the addition of malaria therapy, whereas the other patient had negative reactions to the tests. One other patient received sodium N-phenylglycinamide-p-arsenate (tryparsamide) without benefit to the spinal fluid.

There were 3 cases in which reactions to tests of the spinal fluid relapsed and became negative with additional treatment. Reactions to tests of the fluid of 1 of the patients relapsed on routine treatment, and the

TABLE 1.—General Classification by Group of Spinal Fluid According to the Degree of Abnormality Found on Examination by Each of the Four Indicated Procedures

Group	Reaction to Test Indicated		Cells per Cu. Mm.	Colloidal Benzoin or Gold Curve

† Polymorphonuclear cells.

spinal fluid became normal with the addition of intraspinal treatment. The second patient required therapy with malaria to bring about the desired normality of the spinal fluid, whereas the spinal fluid of the third patient reverted to normal with further intraspinal treatment and remained normal.

In 17 of 28 cases reactions to tests of the cerebrospinal fluid that became negative did so within a year or less; reactions in 6 more cases became negative within one to two years, whereas in the other 5 cases the reactions became negative within two to nine years.

The 32 patients who had asymptomatic neurosyphilis received from one to thirteen intraspinal treatments each, in addition to arsphenamine, a heavy metal and iodides; of these 32 patients, 29 received three or more intraspinal treatments in conjunction with routine treatment. These 29 patients underwent a total of two hundred and thirty-eight intraspinal treatments, an average of eight per patient.

Symptomatic neurosyphilis did not afflict any patient in the group.
